nag_opt_simplex (e04ccc)

1. Purpose

nag_opt_simplex (e04ccc) minimizes a general function $F(x)$ of $n$ independent variables $x = (x_1, x_2, \ldots, x_n)^T$ by the Simplex method. No derivatives are required.

2. Specification

```c
#include <stdio.h>
#include <nage04.h>
void nag_opt_simplex(Integer n,
                      void (*funct)(Integer n, double *xc, double *fc, Nag_Comm *comm),
                      double x[], double *fmin, Nag_E04_Opt *options, Nag_Comm *user_comm,
                      NagError *fail)
```

3. Description

nag_opt_simplex finds an approximation to a minimum of a function $F(x)$ of $n$ variables. The user must supply a function to calculate the value of $F(x)$ for any set of values of the variables.

The method is iterative. A simplex of $n+1$ points is set up in the dimensional space of the variables (for example, in 2 dimensions the simplex is a triangle) under the assumption that the problem has been scaled so that the values of the independent variables at the minimum are of order unity. The starting point provided by the user is the first vertex of the simplex, the remaining $n$ vertices are generated internally (see Parkinson and Hutchinson (1972)). The vertex of the simplex with the largest function value is reflected in the centre of gravity of the remaining vertices and the function value at this new point is compared with the remaining function values. Depending on the outcome of this test the new point is accepted or rejected, a further expansion move may be made, or a contraction may be carried out. When no further progress can be made the sides of the simplex are reduced in length and the method is repeated.

The method tends to be slow, but it is robust and therefore very useful for functions that are subject to inaccuracies.

4. Parameters

$n$

Input: $n$, the number of independent variables.
Constraint: $n \geq 1$.

`funct`

The function `funct`, supplied by the user, must calculate the value of $F(x)$ at any point $x$. (However, if the user does not wish to calculate the value of $F(x)$ at a particular $x$, there is the option of setting a parameter to cause `nag_opt_simplex` to terminate immediately.)
The specification of `funct` is:

```c
void funct(Integer n, double xc[], double *fc, Nag_Comm *comm)

n
  Input: n, the number of variables.

xc[n]
  Input: x, the point at which the value of F(x) is required.

fc
  Output: the value of F(x) at the current point x.

comm
  Pointer to structure of type Nag_Comm; the following members are relevant to
  funct.

  flag – Integer
    Input: comm->flag contains a non-negative number.
    Output: if funct resets comm->flag to some negative number then
    nag_opt_simplex will terminate immediately with the error indicator
    NE_USER_STOP. If fail is supplied to nag_opt_simplex, fail.errnum will
    be set to the user’s setting of comm->flag.

  first – Boolean
    Input: will be set to TRUE on the first call to funct and FALSE for all
    subsequent calls.

  nf – Integer
    Input: the number of calls made to funct so far.

user – double *
user – Integer *
p – Pointer
  The type Pointer will be void * with a C compiler that defines void *
  and char * otherwise.
  Before calling nag_opt_simplex these pointers may be allocated memory by
  the user and initialised with various quantities for use by funct when called
  from nag_opt_simplex.
```

Note: `funct` should be tested separately before being used in conjunction with
nag_opt_simplex. The array xc must not be changed within `funct`.

`x[n]`
Input: a guess at the position of the minimum. Note that the problem should be scaled so
that the values of the variables $x_1, x_2, \ldots, x_n$ are of order unity.
Output: the value of $x$ corresponding to the function value returned in `fmin`.

`fmin`
Output: the lowest function value found.

`options`
Input/Output: a pointer to a structure of type Nag_E04_Opt whose members are optional
parameters for nag_opt_simplex. These structure members offer the means of adjusting some
of the parameter values of the algorithm and on output will supply further details of the
results. A description of the members of `options` is given below in Section 7.

If any of these optional parameters are required then the structure `options` should be
declared and initialised by a call to nag_opt_init (e04xxc) and supplied as an argument to
nag_opt_simplex. However, if the optional parameters are not required the NAG defined null
pointer, E04_DEFAULT, can be used in the function call.

`comm`
Input/Output: structure containing pointers for communication to user-supplied functions;
see the above description of `funct` for details. If the user does not need to make use
of this communication feature the null pointer NAGCOMM_NULL may be used in the call to
nag_opt_simplex; comm will then be declared internally for use in calls to user-supplied functions.

fail
The NAG error parameter, see the Essential Introduction to the NAG C Library.
Users are recommended to declare and initialise fail and set fail.print = TRUE for this function.

4.1. Description of Printed Output

Intermediate and final results are printed out by default. The level of printed output can be controlled by the user with the option print_level (see Section 7.2.). The default print level of Nag_Soln_Iter provides a single line of output at each iteration and the final result.

The line of results printed at each iteration gives:

<table>
<thead>
<tr>
<th>Itn</th>
<th>the current iteration number $k$.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nfun</td>
<td>the cumulative number of calls to lsqfun.</td>
</tr>
<tr>
<td>Objective</td>
<td>the current value of the objective function, $F(x^{(k)})$.</td>
</tr>
<tr>
<td>Norm g</td>
<td>the Euclidean norm of the gradient of $F(x^{(k)})$.</td>
</tr>
<tr>
<td>Norm x</td>
<td>the Euclidean norm of $x^{(k)}$.</td>
</tr>
<tr>
<td>Norm(x(k-1)-x(k))</td>
<td>the Euclidean norm of $x^{(k-1)} - x^{(k)}$.</td>
</tr>
<tr>
<td>Step</td>
<td>the step $\alpha^{(k)}$ taken along the computed search direction $p^{(k)}$.</td>
</tr>
</tbody>
</table>

The printout of the final result consists of:

<table>
<thead>
<tr>
<th>x</th>
<th>the final point $x^*$.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function value</td>
<td>the value of $F(x^*)$.</td>
</tr>
</tbody>
</table>

5. Comments

A list of possible error exits and warnings from nag_opt_simplex is given in Section 8.

5.1. Accuracy

On a successful exit the accuracy will be as defined by options.optim_tol (see Section 7.2.).

6. Example 1

A simple program to locate a minimum of the function:

$$F = e^{x_1} (4x_1^2 + 2x_2^2 + 4x_1x_2 + 2x_2 + 1).$$

The program uses $(-1.0, 1.0)$ as the initial guess at the position of the minimum.

This example shows the simple use of nag_opt_simplex where default values are used for all optional parameters. An example showing the use of optional parameters is given in Section 12. There is however only one example program file, the main program of which calls both examples. The main program and example 1 are given below.

6.1. Example Text

</tbody>
</table>

Final solution:

Vector x
5.0005e-01
-1.0001e+00

Final Function value is 9.7190e-09

7. Optional Parameters

A number of optional input and output parameters to nag_opt_simplex are available through the structure argument options, type Nag_E04_Opt. A parameter may be selected by assigning an appropriate value to the relevant structure member; those parameters not selected will be assigned default values. If no use is to be made of any of the optional parameters the user should use the NAG defined null pointer, E04_DEFAULT, in place of options when calling nag_opt_simplex; the default settings will then be used for all parameters.

Before assigning values to options directly the structure must be initialised by a call to the function
nag_opt_simplex

nag_opt_init (e04xic). Values may then be assigned to the structure members in the normal C manner.

Option settings may also be read from a text file using the function nag_opt_read (e04xic) in which case initialisation of the options structure will be performed automatically if not already done. Any subsequent direct assignment to the options structure must not be preceded by initialisation.

If an assignment of a function pointer in the options structure is required, this must be done directly in the calling program, it cannot be assigned using nag_opt_read (e04xic).

7.1. Optional Parameter Checklist and Default Values

For easy reference, the following list shows the members of options which are valid for nag_opt_simplex together with their default values where relevant. The number \( \epsilon \) is a generic notation for machine precision (see nag_machine_precision (X02AJC)).

Boolean list

<table>
<thead>
<tr>
<th>Boolean list</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nag_PrintType print_level</td>
<td>TRUE</td>
</tr>
<tr>
<td>char outfile[80]</td>
<td>stdout</td>
</tr>
<tr>
<td>void (*print_fun)()</td>
<td>NULL</td>
</tr>
<tr>
<td>Integer max_iter</td>
<td>1500</td>
</tr>
<tr>
<td>double optim_tol</td>
<td>( \epsilon )</td>
</tr>
<tr>
<td>Integer iter</td>
<td></td>
</tr>
<tr>
<td>Integer nf</td>
<td></td>
</tr>
</tbody>
</table>

7.2. Description of Optional Parameters

list – Boolean

Input: if options.list = TRUE the parameter settings in the call to nag_opt_simplex will be printed.

Default = TRUE

Input: if options.print_level = Nag_NoPrint or Nag_Soln or Nag_Iter or Nag_Soln_Iter or Nag_Soln_Iter_Full.

outfile – char[80]

Input: the name of the file to which results should be printed. If options.outfile[0] = '\0' then the stdout stream is used.

Default = stdout

Input: printing function defined by the user; the prototype of print_fun is

\[
\text{void (*print_fun)(const Nag_Search_State *st, Nag_Comm *comm)};
\]

See Section 7.3.1. below for further details.

Default = NULL

Input: the maximum number of iterations allowed before termination.

Default = 1500

Constraint: options.max_iter > 0.

optim_tol – double

Input: the accuracy in \( x \) to which the solution is required. If \( f_i, \text{ for } i = 1, 2, \ldots, n + 1, \) are the individual function values at the vertices of a simplex and \( f_m \) is the mean of these values, then termination will occur when

\[
\sqrt{\frac{1}{n+1} \sum_{i=1}^{n+1} (f_i - f_m)^2} \leq \text{options.optim_tol}.
\]

Constraint: options.optim_tol \( \geq \epsilon \).
iter – Integer
Output: the number of iterations which have been performed by nag_opt_simplex.

nf – Integer
Output: the number of times that funct has been called.

7.3. Description of Printed Output

The level of printed output can be controlled with the structure members options.list and
options.print_level (see Section 7.2.). If list = TRUE then the parameter values to nag_opt_simplex
are listed, whereas the printout of results is governed by the value of print_level. The default of
print_level = Nag_Soln_Iter provides a single line of output at each iteration and the final result.
This section describes all of the possible levels of results printout available from nag_opt_simplex.

When options.print_level = Nag_Iter or Nag_Soln_Iter a single line of output is produced on
completion of each iteration, this gives the following values:

| Itn | the current iteration number k. |
| Nfun | the cumulative number of calls made to funct. |
| Fmin | the smallest function value in the current simplex. |
| Fmax | the largest function value in the current simplex. |

When options.print_level = Nag_Soln_Iter_Full more detailed results are given at each iteration.
Additional values output are

- x the current point \( x^{(k)} \).
- Simplex Vertices of the simplex with their corresponding vectors containing the
  positions of the current simplex.

If options.print_level = Nag_Soln or Nag_Soln_Iter or Nag_Soln_Iter_Full the final result is printed.
This consists of:

- x the final point \( x^* \).
- Function value the value of \( F(x^*) \).

If options.print_level = Nag_NoPrint, printout will be suppressed; the user can then print the final
solution when nag_opt_simplex returns to the calling program.

7.3.1. Output of results via a user defined printing function

Users may also specify their own print function for output of iteration results and the final solution
by use of the options.print_fun function pointer, which has prototype

```c
void (*print_fun)(const Nag_Search_State *st, Nag_Comm *comm);
```

The rest of this section can be skipped if the default printing facilities provide the required
functionality.

When a user defined function is assigned to options.print_fun this will be called in preference to the
internal print function of nag_opt_simplex. Calls to the user defined function are again controlled
by means of the options.print_level member. Information is provided through st and comm, the
two structure arguments to print_fun. If comm->it prt = TRUE then the results from the last
iteration of nag_opt_simplex are in the following members of st:

- n – Integer
  the number of variables.
- x – double *
  points to the n memory locations holding the current point \( x^{(k)} \).
- fmin – double
  holds the smallest function value in the current simplex.
- fmax – double
  holds the largest function value in the current simplex.
- simplex – double *
  points to the \((n+1)^*n\) memory locations. If we regard this pointer as pointing to a notional
  2-D array then its \(n+1\) rows contain the n position vectors of the vertices of the current
  simplex.
nag\_opt\_simplex

iter – Integer
   \(k\), the number of iterations performed by nag\_opt\_simplex.

nf – Integer
   the cumulative number of calls made to funct.

The relevant members of the structure comm are:

it\_prt – Boolean
   will be \textsc{true} when the print function is called with the result of the current iteration.

sol\_prt – Boolean
   will be \textsc{true} when the print function is called with the final result.

user – double *

iuser – Integer *

p – Pointer
   pointers for communication of user information. If used they must be allocated memory by
   the user either before entry to nag\_opt\_simplex or during a call to funct or print\_fun. The
   type Pointer will be \texttt{void *} with a C compiler that defines \texttt{void *}
   and \texttt{char *} otherwise.

8. Error Indications and Warnings

\texttt{NE\_INT\_ARG\_LT}
   On entry, \(n\) must not be less than 1: \(n = \langle \text{value} \rangle\).

\texttt{NE\_OPT\_NOT\_INIT}
   Options structure not initialised.

\texttt{NE\_BAD\_PARAM}
   On entry, parameter \texttt{options.print\_level} had an illegal value.

\texttt{NE\_INVALID\_INT\_RANGE\_1}
   Value \(\langle \text{value} \rangle\) given to \texttt{options.max\_iter} is not valid. Correct range is \texttt{options.max\_iter} > 0.

\texttt{NE\_INVALID\_REAL\_RANGE\_E}
   Value \(\langle \text{value} \rangle\) given to \texttt{options.optim\_tol} is not valid. Correct range is \texttt{options.optim\_tol} \(\geq \varepsilon\).

\texttt{NE\_NOT\_APPEND\_FILE}
   Cannot open file \(\langle \text{string} \rangle\) for appending.

\texttt{NE\_NOT\_CLOSE\_FILE}
   Cannot close file \(\langle \text{string} \rangle\).

\texttt{NE\_ALLOC\_FAIL}
   Memory allocation failed.

\texttt{NW\_TOO\_MANY\_ITER}
   The maximum number of iterations, \(\langle \text{value} \rangle\), have been performed.
   \texttt{options.max\_iter} evaluations of \(F(x)\) have been completed, nag\_opt\_simplex has been
   terminated prematurely. Check the coding of the function funct before increasing the value
   of \texttt{options.max\_iter}.

\texttt{NE\_USER\_STOP}
   User requested termination, user flag value = \(\langle \text{value} \rangle\)

   This exit occurs if the user sets comm\_flag to a negative value in funct. If fail is supplied
   the value of fail.errnum will be the same as the user’s setting of comm\_flag.

9. Further Comments

The time taken depends on the number of variables, the behaviour of \(F(x)\) and the distance of the
starting point from the minimum. Each iteration consists of 1 or 2 evaluations of \(F(x)\) unless the
size of the simplex is reduced, in which case \(n + 1\) evaluations are required.

12. Example 2

Example 2 solves the same problem as Example 1 but shows the use of certain optional parameters.
This example shows option values being assigned directly within the program text and by reading
values from a data file. The options structure is declared and initialised by nag_opt_init (e04xic),
a value is then assigned directly to the print_fun option. One further option, optim_tol is read
from the data file by the use of nag_opt_read (e04xyc).

optim_tol set to 1.00e-14
e04 – Minimizing or Maximizing a Function

Parameters to e04ccc
---------------------

Number of variables........... 2
optim_tol............... 1.00e-14 max_iter............... 1500
print_level.........Nag_Soln_Iter machine precision...... 1.11e-16
outfile.................. stdout

After 20 iteration and 44 function calls, the function value is 2.0075e-04
The simplex is
  5.0050e-01 -1.0083e+00
  5.1487e-01 -1.0182e+00
  5.1090e-01 -1.0008e+00

After 40 iteration and 83 function calls, the function value is 6.6865e-10
The simplex is
  5.0001e-01 -1.0000e+00
  5.0001e-01 -1.0000e+00
  4.9999e-01 -1.0000e+00
The final solution is
  5.0000e-01
  -1.0000e+00
After 58 iterations and 119 function calls the function
value at the current solution point is 2.9287e-15.
