NAG Library Function Document

nag_lambertW (c05bac)

1 Purpose

nag_lambertW (c05bac) returns the real values of Lambert's $W$ function $W(x)$.

2 Specification

```c
#include <nag.h>
#include <nagc05.h>

double nag_lambertW (double x, Integer branch, Nag_Boolean offset, NagError *fail)
```

3 Description

nag_lambertW (c05bac) calculates an approximate value for the real branches of Lambert's $W$ function (sometimes known as the 'product log' or 'Omega' function), which is the inverse function of

$$f(w) = we^w \quad \text{for} \quad w \in \mathbb{C}.$$ 

The function $f$ is many-to-one, and so, except at 0, $W$ is multivalued. nag_lambertW (c05bac) restricts $W$ and its argument $x$ to be real, resulting in a function defined for $x \geq -\exp(-1)$ and which is double valued on the interval $(-\exp(-1), 0)$. This double-valued function is split into two real-valued branches according to the sign of $W(x) + 1$. We denote by $W_0$ the branch satisfying $W_0(x) \geq -1$ for all real $x$, and by $W_{-1}$ the branch satisfying $W_{-1}(x) \leq -1$ for all real $x$. You may select your branch of interest using the argument `branch`.

The precise method used to approximate $W$ is described fully in Barry et al. (1995). For $x$ close to $-\exp(-1)$ greater accuracy comes from evaluating $W(-\exp(-1) + \Delta x)$ rather than $W(x)$: by setting `offset = Nag_TRUE` on entry you inform nag_lambertW (c05bac) that you are providing $\Delta x$, not $x$, in $x$.

4 References

5 Arguments

1:  
   `x` – double
   
   **Input**
   
   On entry: if `offset = Nag_TRUE`, `x` is the offset $\Delta x$ from $-\exp(-1)$ of the intended argument to $W$; that is, $W(\beta)$ is computed, where $\beta = -\exp(-1) + \Delta x$.
   
   If `offset = Nag_FALSE`, `x` is the argument $x$ of the function; that is, $W(\beta)$ is computed, where $\beta = x$.
   
   **Constraints:**
   
   if `branch = 0`, $-\exp(-1) \leq \beta$;
   
   if `branch = -1`, $-\exp(-1) \leq \beta < 0.0$.

2:  
   `branch` – Integer
   
   **Input**
   
   On entry: the real branch required.
   
   `branch = 0`
   
   The branch $W_0$ is selected.
branch = -1
The branch $W_{-1}$ is selected.

Constraint: branch = 0 or -1.

3: offset – Nag_Boolean

On entry: controls whether or not $x$ is being specified as an offset from $-\exp(-1)$.

4: fail – NagError *

The NAG error argument (see Section 3.6 in the Essential Introduction).

6 Error Indicators and Warnings

NE_ALLOC_FAIL

Dynamic memory allocation failed.
See Section 3.2.1.2 in the Essential Introduction for further information.

NE_INT

On entry, branch = (value).
Constraint: branch = 0 or -1.

NE_INTERNAL_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.

An unexpected error has been triggered by this function. Please contact NAG.
See Section 3.6.6 in the Essential Introduction for further information.

NE_NO_LICENCE

Your licence key may have expired or may not have been installed correctly.
See Section 3.6.5 in the Essential Introduction for further information.

NE_REAL

On entry, branch = -1, offset = Nag_FALSE and $x$ = (value).
Constraint: if branch = -1 and offset = Nag_FALSE then $x < 0.0$.

On entry, branch = -1, offset = Nag_TRUE and $x$ = (value).
Constraint: if branch = -1 and offset = Nag_TRUE then $x < \exp(-1.0)$.

On entry, offset = Nag_TRUE and $x$ = (value).
Constraint: if offset = Nag_TRUE then $x \geq 0.0$.

On entry, offset = Nag_FALSE and $x$ = (value).
Constraint: if offset = Nag_FALSE then $x \geq -\exp(-1.0)$.

NW_REAL

For the given offset $x$, $W$ is negligibly different from $-1$: $x$ = (value).

$x$ is close to $-\exp(-1)$. Enter $x$ as an offset to $-\exp(-1)$ for greater accuracy: $x$ = (value).

7 Accuracy

For a high percentage of legal $x$ on input, nag_lambertW (c05bac) is accurate to the number of decimal digits of precision on the host machine (see nag_decimal_digits (X02BEC)). An extra digit may be lost on some implementations and for a small proportion of such $x$. This depends on the accuracy of the base-10 logarithm on your system.
8 Parallelism and Performance
Not applicable.

9 Further Comments
None.

10 Example
This example reads from a file the values of the required branch, whether or not the arguments to $W$ are to be considered as offsets to $-\exp(-1)$, and the arguments $x$ themselves. It then evaluates the function for these sets of input data $x$ and prints the results.
