NAG Library Function Document

nag_matop_real_gen_matrix_log (f01ejc)

1 Purpose
nag_matop_real_gen_matrix_log (f01ejc) computes the principal matrix logarithm, \( \log(A) \), of a real \( n \) by \( n \) matrix \( A \), with no eigenvalues on the closed negative real line.

2 Specification

```c
#include <nag.h>
#include <nagf01.h>
void nag_matop_real_gen_matrix_log (Nag_OrderType order, Integer n,
                                   double a[], Integer pda, Double *imnorm, NagError *fail)
```

3 Description

Any nonsingular matrix \( A \) has infinitely many logarithms. For a matrix with no eigenvalues on the closed negative real line, the principal logarithm is the unique logarithm whose spectrum lies in the strip \( \{ z : -\pi < \text{Im}(z) < \pi \} \).

\( \log(A) \) is computed using the inverse scaling and squaring algorithm for the matrix logarithm described in Al–Mohy and Higham (2011), adapted to real matrices by Al–Mohy et al. (2012).

4 References

5 Arguments

1: order – Nag_OrderType

   On entry: the order argument specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by order = Nag_RowMajor. See Section 3.2.1.3 in the Essential Introduction for a more detailed explanation of the use of this argument.

   Constraint: order = Nag_RowMajor or Nag_ColMajor.

2: n – Integer

   On entry: \( n \), the order of the matrix \( A \).

   Constraint: \( n \geq 0 \).

3: a[dim] – double

   Note: the dimension, \( \text{dim} \), of the array \( a \) must be at least \( pda \times n \).

   The \( (i,j) \)th element of the matrix \( A \) is stored in 
   
   \( a[(j-1) \times pda + i - 1] \) when order = Nag_ColMajor;
   \( a[(i-1) \times pda + j - 1] \) when order = Nag_RowMajor.
On entry: the $n$ by $n$ matrix $A$.

On exit: the $n$ by $n$ principal matrix logarithm, $\log(A)$.

4: pda – Integer

On entry: the stride separating row or column elements (depending on the value of order) in the array a. 

Constraint: $\text{pda} \geq n$.

5: imnorm – double *

On exit: if the function has given a reliable answer then $\text{imnorm} = 0.0$. If $\text{imnorm}$ differs from 0.0 by more than unit roundoff (as returned by nag_machine_precision (X02AJC)) then the computed matrix logarithm is unreliable.

6: fail – NagError *

The NAG error argument (see Section 3.6 in the Essential Introduction).

6 Error Indicators and Warnings

**NE_ALLOC_FAIL**
Dynamic memory allocation failed.
See Section 3.2.1.2 in the Essential Introduction for further information.

**NE_BAD_PARAM**
On entry, argument $\langle$value$\rangle$ had an illegal value.

**NE_EIGENVALUES**

$A$ was found to have eigenvalues on the negative real line. The principal logarithm is not defined in this case. nag_matop_complex_gen_matrix_log (f01fjc) can be used to find a complex non-principal logarithm.

**NE_INT**
On entry, $n = \langle$value$\rangle$.
Constraint: $n \geq 0$.

**NE_INT_2**
On entry, $\text{pda} = \langle$value$\rangle$ and $n = \langle$value$\rangle$.
Constraint: $\text{pda} \geq n$.

**NE_INTERNAL_ERROR**

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.

An unexpected error has been triggered by this function. Please contact NAG. See Section 3.6.6 in the Essential Introduction for further information.

**NE_NO_LICENCE**
Your licence key may have expired or may not have been installed correctly. See Section 3.6.5 in the Essential Introduction for further information.

**NE_SINGULAR**

$A$ is singular so the logarithm cannot be computed.
NW_SOME_PRECISION_LOSS

log(A) has been computed using an IEEE double precision Padé approximant, although the arithmetic precision is higher than IEEE double precision.

7 Accuracy

For a normal matrix A (for which \(A^T A = AA^T\), the Schur decomposition is diagonal and the algorithm reduces to evaluating the logarithm of the eigenvalues of A and then constructing log(A) using the Schur vectors. This should give a very accurate result. In general, however, no error bounds are available for the algorithm. See Al–Mohy and Higham (2011) and Section 9.4 of Higham (2008) for details and further discussion.

The sensitivity of the computation of log(A) is worst when A has an eigenvalue of very small modulus or has a complex conjugate pair of eigenvalues lying close to the negative real axis.

If estimates of the condition number of the matrix logarithm are required then nag_matop_real_gen_matrix_cond_log (f01jjc) should be used.

8 Parallelism and Performance

nag_matop_real_gen_matrix_log (f01ejc) is threaded by NAG for parallel execution in multithreaded implementations of the NAG Library.

nag_matop_real_gen_matrix_log (f01ejc) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users’ Note for your implementation for any additional implementation-specific information.

9 Further Comments

The cost of the algorithm is \(O(n^3)\) floating-point operations (see Al–Mohy and Higham (2011)). The double allocatable memory required is approximately \(3 \times n^2\).

If the Fréchet derivative of the matrix logarithm is required then nag_matop_real_gen_matrix_frcht_log (f01jkc) should be used.

nag_matop_complex_gen_matrix_log (f01fjc) can be used to find the principal logarithm of a complex matrix. It can also be used to return a complex, non-principal logarithm if a real matrix has no principal logarithm due to the presence of negative eigenvalues.

10 Example

This example finds the principal matrix logarithm of the matrix

\[
A = \begin{pmatrix} 3 & -3 & 1 & 1 \\ 2 & 1 & -2 & 1 \\ 1 & 1 & 3 & -1 \\ 2 & 0 & 2 & 0 \end{pmatrix}.
\]
