NAG Library Function Document
nag_matop_real_gen_matrix_pow (f01eqc)

1 Purpose
nag_matop_real_gen_matrix_pow (f01eqc) computes the principal real power $A^p$, for arbitrary $p$, of an $n$ by $n$ matrix $A$.

2 Specification
#include <nag.h>
#include <nagf01.h>

void nag_matop_real_gen_matrix_pow (Integer n, double a[], Integer pda, double p, NagError *fail)

3 Description
For a matrix $A$ with no eigenvalues on the closed negative real line, $A^p \ (p \in \mathbb{R})$ can be defined as

$$A^p = \exp(p \log(A))$$

where $\log(A)$ is the principal logarithm of $A$ (the unique logarithm whose spectrum lies in the strip \( \{ z : -\pi < \text{Im}(z) < \pi \} \)).

$A^p$ is computed using the real version of the Schur–Padé algorithm described in Higham and Lin (2011) and Higham and Lin (2013).

The real number $p$ is expressed as $p = q + r$ where $q \in (-1, 1)$ and $r \in \mathbb{Z}$. Then $A^p = A^q A^r$. The integer power $A^r$ is found using a combination of binary powering and, if necessary, matrix inversion. The fractional power $A^q$ is computed, entirely in real arithmetic, using a real Schur decomposition and a Padé approximant.

4 References

5 Arguments
1: n – Integer
   On entry: $n$, the order of the matrix $A$.
   Constraint: $n \geq 0$.

2: a[dim] – double
   On entry: the $n$ by $n$ matrix $A$.
3: \textbf{pda} – Integer \textit{Input} \\
\textit{On entry}: the stride separating matrix row elements in the array \textbf{a}.
\textit{Constraint}: \textbf{pda} \geq n.

4: \textbf{p} – double \textit{Input} \\
\textit{On entry}: the required power of \textbf{A}.

5: \textbf{fail} – NagError * \textit{Input/Output} \\
The NAG error argument (see Section 3.6 in the Essential Introduction).

6 \hspace{1em} \textbf{Error Indicators and Warnings}

\textbf{NE_ALLOC_FAIL} \\
Dynamic memory allocation failed.
See Section 3.2.1.2 in the Essential Introduction for further information.

\textbf{NE_BAD_PARAM} \\
\textit{On entry}, argument \textit{\langle value\rangle} had an illegal value.

\textbf{NE_INT} \\
\textit{On entry}, \(n = \text{\langle value\rangle}\).
\textit{Constraint}: \(n \geq 0\).

\textbf{NE_INT_2} \\
\textit{On entry}, \textbf{pda} = \text{\langle value\rangle} and \(n = \text{\langle value\rangle}\).
\textit{Constraint}: \textbf{pda} \geq n.

\textbf{NE_INTERNAL_ERROR} \\
An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.
An unexpected error has been triggered by this function. Please contact NAG.
See Section 3.6.6 in the Essential Introduction for further information.

\textbf{NE_NEGATIVE_EIGVAL} \\
\textbf{A} has eigenvalues on the negative real line. The principal \(p\)th power is not defined.
nag_matop_complex_gen_matrix_pow (f01fqc) can be used to find a complex, non-principal \(p\)th power.

\textbf{NE_NO_LICENCE} \\
Your licence key may have expired or may not have been installed correctly.
See Section 3.6.5 in the Essential Introduction for further information.

\textbf{NE_SINGULAR} \\
\textbf{A} is singular so the \(p\)th power cannot be computed.

\textbf{NW_SOME_PRECISION_LOSS} \\
\textbf{A}^p has been computed using an IEEE double precision Padé approximant, although the arithmetic precision is higher than IEEE double precision.
7 Accuracy

For positive integer \( p \), the algorithm reduces to a sequence of matrix multiplications. For negative integer \( p \), the algorithm consists of a combination of matrix inversion and matrix multiplications.

For a normal matrix \( A \) (for which \( A^T A = AA^T \)) and non-integer \( p \), the Schur decomposition is diagonal and the algorithm reduces to evaluating powers of the eigenvalues of \( A \) and then constructing \( A^p \) using the Schur vectors. This should give a very accurate result. In general however, no error bounds are available for the algorithm.

8 Parallelism and Performance

\texttt{nag_matop_real_gen_matrix_pow (f01eqc)} is threaded by NAG for parallel execution in multithreaded implementations of the NAG Library.

\texttt{nag_matop_real_gen_matrix_pow (f01eqc)} makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users’ Note for your implementation for any additional implementation-specific information.

9 Further Comments

The cost of the algorithm is \( O(n^3) \). The exact cost depends on the matrix \( A \) but if \( p \in (-1, 1) \) then the cost is independent of \( p \). \( O(4 \times n^2) \) of real allocatable memory is required by the function.

If estimates of the condition number of \( A^p \) are required then \texttt{nag_matop_real_gen_matrix_cond_pow (f01jec)} should be used.

10 Example

This example finds \( A^p \) where \( p = 0.2 \) and

\[
A = \begin{pmatrix}
3 & 3 & 2 & 1 \\
3 & 1 & 0 & 2 \\
1 & 1 & 4 & 3 \\
3 & 0 & 3 & 1
\end{pmatrix}.
\]
