NAG Library Function Document

nag_matop_complex_gen_matrix_fun_num (f01flc)

1 Purpose

nag_matop_complex_gen_matrix_fun_num (f01flc) computes the matrix function, \( f(A) \), of a complex \( n \) by \( n \) matrix \( A \). Numerical differentiation is used to evaluate the derivatives of \( f \) when they are required.

2 Specification

```c
#include <nag.h>
#include <nagf01.h>

void nag_matop_complex_gen_matrix_fun_num (Integer n, Complex a[],
          Integer pda,
          void (*f)(Integer *iflag, Integer nz, const Complex z[], Complex fz[],
                    Nag_Comm *comm),
          Nag_Comm *comm, Integer *iflag, NagError *fail)
```

3 Description

\( f(A) \) is computed using the Schur–Parlett algorithm described in Higham (2008) and Davies and Higham (2003). The coefficients of the Taylor series used in the algorithm are evaluated using the numerical differentiation algorithm of Lyness and Moler (1967).

The scalar function \( f \) is supplied via function \( f \) which evaluates \( f(z_i) \) at a number of points \( z_i \).

4 References

5 Arguments

1: \( n \) – Integer

*Input*

\( On \ entry: n \), the order of the matrix \( A \).

\( Constraint: n \geq 0. \)

2: \( a[dim] \) – Complex

*Input/Output*

\( Note: \) the dimension, \( dim \), of the array \( a \) must be at least \( pda \times n \).

The \((i,j)\)th element of the matrix \( A \) is stored in \( a[(j-1) \times pda + i-1] \).

\( On \ entry: \) the \( n \) by \( n \) matrix \( A \).

\( On \ exit: \) the \( n \) by \( n \) matrix, \( f(A) \).

3: \( pda \) – Integer

*Input*

\( On \ entry: \) the stride separating matrix row elements in the array \( a \).

\( Constraint: pda \geq n. \)
4: \( f \) – function, supplied by the user

The function \( f \) evaluates \( f(z_i) \) at a number of points \( z_i \).

</tbody>
</table>
6 Error Indicators and Warnings

**NE_ALLOC_FAIL**
Dynamic memory allocation failed.
See Section 3.2.1.2 in the Essential Introduction for further information.

**NE_BAD_PARAM**
On entry, argument $\langle$value$\rangle$ had an illegal value.

**NE_CONVERGENCE**
A Taylor series failed to converge after 40 terms. Further Taylor series coefficients can no longer reliably be obtained by numerical differentiation.

**NE_INT**
On entry, $n = \langle$value$\rangle$.
Constraint: $n \geq 0$.

**NE_INT_2**
On entry, $pda = \langle$value$\rangle$ and $n = \langle$value$\rangle$.
Constraint: $pda \geq n$.

**NE_INTERNAL_ERROR**
An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.
An unexpected error has been triggered by this function. Please contact NAG.
See Section 3.6.6 in the Essential Introduction for further information.
An unexpected internal error occurred when ordering the eigenvalues of $A$. Please contact NAG.
The function was unable to compute the Schur decomposition of $A$.
**Note:** this failure should not occur and suggests that the function has been called incorrectly.
There was an error whilst reordering the Schur form of $A$.
**Note:** this failure should not occur and suggests that the function has been called incorrectly.

**NE_NO_LICENCE**
Your licence key may have expired or may not have been installed correctly.
See Section 3.6.5 in the Essential Introduction for further information.

**NE_USER_STOP**
iflag has been set nonzero by the user.

7 Accuracy
For a normal matrix $A$ (for which $A^H A = AA^H$) Schur decomposition is diagonal and the algorithm reduces to evaluating $f$ at the eigenvalues of $A$ and then constructing $f(A)$ using the Schur vectors. See Section 9.4 of Higham (2008) for further discussion of the Schur–Parlett algorithm, and Lyness and Moler (1967) for a discussion of numerical differentiation.

8 Parallelism and Performance
nag_matop_complex_gen_matrix_fun_num (f01flc) is threaded by NAG for parallel execution in multithreaded implementations of the NAG Library. In these implementations, this function may make calls to the user-supplied functions from within an OpenMP parallel region. Thus OpenMP pragmas within the user functions can only be used if you are compiling the user-supplied function and linking...
the executable in accordance with the instructions in the Users’ Note for your implementation. You must
also ensure that you use the NAG communication argument comm in a thread safe manner, which is best
achieved by only using it to supply read-only data to the user functions.
nag_matop_complex_gen_matrix_fun_num (f01flc) makes calls to BLAS and/or LAPACK routines,
which may be threaded within the vendor library used by this implementation. Consult the
documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the
OpenMP environment used within this function. Please also consult the Users’ Note for your
implementation for any additional implementation-specific information.

9 Further Comments

The Integer allocatable memory required is \( n \), and up to \( 6n^2 \) of Complex allocatable memory is required.
The cost of the Schur–Parlett algorithm depends on the spectrum of \( A \), but is roughly between \( 28n^3 \) and
\( n^4/3 \) floating-point operations. There is an additional cost in numerically differentiating \( f \), in order to
obtain the Taylor series coefficients. If the derivatives of \( f \) are known analytically, then
nag_matop_complex_gen_matrix_fun_usd (f01fmc) can be used to evaluate \( f(A) \) more accurately. If
\( A \) is complex Hermitian then it is recommended that nag_matop_complex_herm_matrix_fun (f01ffc) be
used as it is more efficient and, in general, more accurate than
nag_matop_complex_gen_matrix_fun_num (f01flc).

Note that \( f \) must be analytic in the region of the complex plane containing the spectrum of \( A \).

For further information on matrix functions, see Higham (2008).

If estimates of the condition number of the matrix function are required then
nag_matop_complex_gen_matrix Cond_num (f01kbc) should be used.
nag_matop_real_gen_matrix_fun_num (f01elc) can be used to find the matrix function \( f(A) \) for a real
matrix \( A \).

10 Example

This example finds \( \sin 2A \) where

\[
A = \begin{pmatrix}
1.0 + 0.0i & 0.0 + 1.0i & 1.0 + 0.0i & 0.0 + 1.0i \\
-1.0 + 0.0i & 0.0 + 0.0i & 2.0 + 1.0i & 0.0 + 0.0i \\
0.0 + 0.0i & 2.0 + 1.0i & 0.0 + 2.0i & 0.0 + 1.0i \\
1.0 + 0.0i & 1.0 + 1.0i & -1.0 + 0.0i & 2.0 + 1.0i
\end{pmatrix}.
\]
