NAG Library Function Document
nag_real_tridiag_lin_solve (f04bcc)

1 Purpose

nag_real_tridiag_lin_solve (f04bcc) computes the solution to a real system of linear equations $AX = B$, where $A$ is an $n$ by $n$ tridiagonal matrix and $X$ and $B$ are $n$ by $r$ matrices. An estimate of the condition number of $A$ and an error bound for the computed solution are also returned.

2 Specification

```c
#include <nag.h>
#include <nagf04.h>
void nag_real_tridiag_lin_solve (Nag_OrderType order, Integer n, 
    Integer nrhs, double dl[], double d[], double du[], double du2[], 
    Integer ipiv[], double b[], Integer pdb, double *rcond, double *errbnd, 
    NagError *fail)
```

3 Description

The $LU$ decomposition with partial pivoting and row interchanges is used to factor $A$ as $A = PLU$, where $P$ is a permutation matrix, $L$ is unit lower triangular with at most one nonzero subdiagonal element, and $U$ is an upper triangular band matrix with two superdiagonals. The factored form of $A$ is then used to solve the system of equations $AX = B$.

Note that the equations $A^TX = B$ may be solved by interchanging the order of the arguments $du$ and $dl$.

4 References

5 Arguments

1:  **order** – Nag_OrderType

   On entry: the argument specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by `order = Nag_RowMajor`. See Section 3.2.1.3 in the Essential Introduction for a more detailed explanation of the use of this argument.

   Constraint: `order = Nag_RowMajor` or `Nag_ColMajor`.

2:  **n** – Integer

   On entry: the number of linear equations $n$, i.e., the order of the matrix $A$.

   Constraint: $n \geq 0$.

3:  **nrhs** – Integer

   On entry: the number of right-hand sides $r$, i.e., the number of columns of the matrix $B$.

   Constraint: $nrhs \geq 0$.
4: \( dl [dim] \) – double

*Input/Output*

**Note:** the dimension, \( dim \), of the array \( dl \) must be at least \( \max(1, n - 1) \).

*On entry:* must contain the \((n - 1)\) subdiagonal elements of the matrix \( A \).

*On exit:* if \( \text{fail.code} = \text{NE_NOERROR} \), \( dl \) is overwritten by the \((n - 1)\) multipliers that define the matrix \( L \) from the \( LU \) factorization of \( A \).

5: \( d [dim] \) – double

*Input/Output*

**Note:** the dimension, \( dim \), of the array \( d \) must be at least \( \max(1, n) \).

*On entry:* must contain the \( n \) diagonal elements of the matrix \( A \).

*On exit:* if \( \text{fail.code} = \text{NE_NOERROR} \), \( d \) is overwritten by the \( n \) diagonal elements of the upper triangular matrix \( U \) from the \( LU \) factorization of \( A \).

6: \( du [dim] \) – double

*Input/Output*

**Note:** the dimension, \( dim \), of the array \( du \) must be at least \( \max(1, n - 1) \).

*On entry:* must contain the \((n - 1)\) superdiagonal elements of the matrix \( A \).

*On exit:* if \( \text{fail.code} = \text{NE_NOERROR} \), \( du \) is overwritten by the \((n - 1)\) elements of the first superdiagonal of \( U \).

7: \( du2 [n - 2] \) – double

*Output*

*On exit:* if \( \text{fail.code} = \text{NE_NOERROR} \), \( du2 \) returns the \((n - 2)\) elements of the second superdiagonal of \( U \).

8: \( ipiv [n] \) – Integer

*Output*

*On exit:* if \( \text{fail.code} = \text{NE_NOERROR} \), the pivot indices that define the permutation matrix \( P \); at the \( i \)th step row \( i \) of the matrix was interchanged with row \( \text{ipiv}[i - 1] \). \( \text{ipiv}[i - 1] \) will always be either \( i \) or \((i + 1)\); \( \text{ipiv}[i - 1] = i \) indicates a row interchange was not required.

9: \( b [dim] \) – double

*Input/Output*

**Note:** the dimension, \( dim \), of the array \( b \) must be at least

\[
\max(1, pdb \times nrhs) \quad \text{when order = Nag_ColMajor;}
\]

\[
\max(1, n \times pdb) \quad \text{when order = Nag_RowMajor.}
\]

The \((i, j)\)th element of the matrix \( B \) is stored in

\[
b[(j - 1) \times pdb + i - 1] \quad \text{when order = Nag_ColMajor;}
\]

\[
b[(i - 1) \times pdb + j - 1] \quad \text{when order = Nag_RowMajor.}
\]

*On entry:* the \( n \) by \( r \) matrix of right-hand sides \( B \).

*On exit:* if \( \text{fail.code} = \text{NE_NOERROR} \) or \( \text{NE_RCOND} \), the \( n \) by \( r \) solution matrix \( X \).

10: \( pdb \) – Integer

*Input*

*On entry:* the stride separating row or column elements (depending on the value of \( \text{order} \)) in the array \( b \).

*Constraints:*

\[
\begin{align*}
\text{if order = Nag_ColMajor,} & \quad pdb \geq \max(1, n); \\
\text{if order = Nag_RowMajor,} & \quad pdb \geq \max(1, nrhs).
\end{align*}
\]

11: \( rcond \) – double *

*Output*

*On exit:* if no constraints are violated, an estimate of the reciprocal of the condition number of the matrix \( A \), computed as \( rcond = \frac{1}{\left(\frac{\|A\|_1}{\|A^{-1}\|_1}\right)} \).
On exit: if \texttt{fail} = \texttt{NE_NOERROR} or \texttt{NE_RCOND}, an estimate of the forward error bound for a computed solution \( \hat{x} \), such that \( \| \hat{x} - x \|_1 / \| x \|_1 \leq \texttt{errbnd} \), where \( \hat{x} \) is a column of the computed solution returned in the array \( b \) and \( x \) is the corresponding column of the exact solution \( X \). If \( \texttt{rcond} \) is less than \textit{machine precision}, then \texttt{errbnd} is returned as unity.

6 Error Indicators and Warnings

\textbf{NE_ALLOC_FAIL}

Dynamic memory allocation failed.
See Section 3.2.1.2 in the Essential Introduction for further information.

\textbf{NE_BAD_PARAM}

On entry, argument \( \langle \text{value} \rangle \) had an illegal value.

\textbf{NE_INT}

On entry, \( n = \langle \text{value} \rangle \).
Constraint: \( n \geq 0 \).
On entry, \( nrhs = \langle \text{value} \rangle \).
Constraint: \( nrhs \geq 0 \).
On entry, \( pdb = \langle \text{value} \rangle \).
Constraint: \( pdb > 0 \).

\textbf{NE_INT_2}

On entry, \( pdb = \langle \text{value} \rangle \) and \( n = \langle \text{value} \rangle \).
Constraint: \( pdb \geq \max(1, n) \).
On entry, \( pdb = \langle \text{value} \rangle \) and \( nrhs = \langle \text{value} \rangle \).
Constraint: \( pdb \geq \max(1, nrhs) \).

\textbf{NE_INTERNAL_ERROR}

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.
An unexpected error has been triggered by this function. Please contact NAG.
See Section 3.6.6 in the Essential Introduction for further information.

\textbf{NE_NO_LICENCE}

Your licence key may have expired or may not have been installed correctly.
See Section 3.6.5 in the Essential Introduction for further information.

\textbf{NE_RCOND}

A solution has been computed, but \texttt{rcond} is less than \textit{machine precision} so that the matrix \( A \) is numerically singular.

\textbf{NE_SINGULAR}

Diagonal element \( \langle \text{value} \rangle \) of the upper triangular factor is zero. The factorization has been completed, but the solution could not be computed.
7 Accuracy
The computed solution for a single right-hand side, \( \hat{x} \), satisfies an equation of the form
\[
(A + E)\hat{x} = b,
\]
where
\[
\|E\|_1 = O(\epsilon)\|A\|_1
\]
and \( \epsilon \) is the machine precision. An approximate error bound for the computed solution is given by
\[
\frac{\|\hat{x} - x\|_1}{\|x\|_1} \leq \kappa(A)\|E\|_1, 
\]
where \( \kappa(A) = \|A^{-1}\|_1\|A\|_1 \), the condition number of \( A \) with respect to the solution of the linear equations. nag_real_tridiag_lin_solve (f04bcc) uses the approximation \( \|E\|_1 = \epsilon\|A\|_1 \) to estimate errbnd. See Section 4.4 of Anderson et al. (1999) for further details.

8 Parallelism and Performance
nag_real_tridiag_lin_solve (f04bcc) is not threaded by NAG in any implementation.

nag_real_tridiag_lin_solve (f04bcc) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users’ Note for your implementation for any additional implementation-specific information.

9 Further Comments
The Integer allocatable memory required is \( n \), and the double allocatable memory required is \( 2 \times n \). In this case the factorization and the solution \( X \) have been computed, but rcond and errbnd have not been computed.

The total number of floating-point operations required to solve the equations \( AX = B \) is proportional to \( nr \). The condition number estimation typically requires between four and five solves and never more than eleven solves, following the factorization.

In practice the condition number estimator is very reliable, but it can underestimate the true condition number; see Section 15.3 of Higham (2002) for further details.

The complex analogue of nag_real_tridiag_lin_solve (f04bcc) is nag_complex_tridiag_lin_solve (f04ccc).

10 Example
This example solves the equations
\[
AX = B,
\]
where \( A \) is the tridiagonal matrix
\[
A = \begin{pmatrix}
3.0 & 2.1 & 0 & 0 & 0 \\
3.4 & 2.3 & -1.0 & 0 & 0 \\
0 & 3.6 & -5.0 & 1.9 & 0 \\
0 & 0 & 7.0 & -0.9 & 8.0 \\
0 & 0 & 0 & -6.0 & 7.1 \\
\end{pmatrix}
\text{ and } B = \begin{pmatrix}
2.7 & 6.6 \\
-0.5 & 10.8 \\
2.6 & -3.2 \\
0.6 & -11.2 \\
2.7 & 19.1 \\
\end{pmatrix}.
\]

An estimate of the condition number of \( A \) and an approximate error bound for the computed solutions are also printed.
