NAG Library Function Document

nag_real_sym_lin_solve (f04bhc)

1 Purpose

nag_real_sym_lin_solve (f04bhc) computes the solution to a real system of linear equations $AX = B$, where $A$ is an $n$ by $n$ symmetric matrix and $X$ and $B$ are $n$ by $r$ matrices. An estimate of the condition number of $A$ and an error bound for the computed solution are also returned.

2 Specification

```c
#include <nag.h>
#include <nagf04.h>

void nag_real_sym_lin_solve (Nag_OrderType order, Nag_UploType uplo,
                           Integer n, Integer nrhs, double a[], Integer pda,
                           Integer ipiv[],
                           double b[], Integer pdb, double *rcond, double *errbnd,
                           NagError *fail)
```

3 Description

The diagonal pivoting method is used to factor $A$ as $A = UDU^T$, if $uplo = Nag_{Upper}$, or $A = LDL^T$, if $uplo = Nag_{Lower}$, where $U$ (or $L$) is a product of permutation and unit upper (lower) triangular matrices, and $D$ is symmetric and block diagonal with 1 by 1 and 2 by 2 diagonal blocks. The factored form of $A$ is then used to solve the system of equations $AX = B$.

4 References

5 Arguments

1:  **order** – Nag_OrderType  
    *Input*
    
    *On entry*: the `order` argument specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by `order = Nag_RowMajor`. See Section 3.2.1.3 in the Essential Introduction for a more detailed explanation of the use of this argument.

    *Constraint*: `order = Nag_RowMajor` or `Nag_ColMajor`.

2:  **uplo** – Nag_UploType  
    *Input*
    
    *On entry*: if `uplo = Nag_Upper`, the upper triangle of the matrix $A$ is stored. If `uplo = Nag_Lower`, the lower triangle of the matrix $A$ is stored.

    *Constraint*: `uplo = Nag_Upper` or `Nag_Lower`.

3:  **n** – Integer  
    *Input*
    
    *On entry*: the number of linear equations $n$, i.e., the order of the matrix $A$.

    *Constraint*: $n \geq 0$. 
4: \textbf{nrhs} – Integer  
\textit{Input}

\textit{On entry}: the number of right-hand sides \( r \), i.e., the number of columns of the matrix \( B \).

\textit{Constraint}: \( \textbf{nrhs} \geq 0 \).

5: \( \textbf{a}[\text{dim}] \) – double  
\textit{Input/Output}

\textit{Note}: the dimension, \( \text{dim} \), of the array \( \textbf{a} \) must be at least \( \max(1, \text{pda} \times \text{n}) \).

The \((i,j)\)th element of the matrix \( A \) is stored in
\[
\begin{align*}
\textbf{a}[ (j-1) \times \text{pda} + i - 1 ] & \text{ when } \text{order} = \text{Nag\_ColMajor}; \\
\textbf{a}[ (i-1) \times \text{pda} + j - 1 ] & \text{ when } \text{order} = \text{Nag\_RowMajor}.
\end{align*}
\]

\textit{On entry}: the \( n \) by \( n \) symmetric matrix \( A \).

\textit{If} \( \text{uplo} = \text{Nag\_Upper} \), the leading \( n \) by \( n \) upper triangular part of the array \( \textbf{a} \) contains the upper triangular part of the matrix \( A \), and the strictly lower triangular part of \( \textbf{a} \) is not referenced.

\textit{If} \( \text{uplo} = \text{Nag\_Lower} \), the leading \( n \) by \( n \) lower triangular part of the array \( \textbf{a} \) contains the lower triangular part of the matrix \( A \), and the strictly upper triangular part of \( \textbf{a} \) is not referenced.

\textit{On exit}: if \textbf{fail.code} = \text{NE\_NOERROR}, the block diagonal matrix \( D \) and the multipliers used to obtain the factor \( U \) or \( L \) from the factorization \( A = UD^T \) or \( A = LDL^T \) as computed by \texttt{nag\_dsytrf (f07mdc)}.

6: \( \textbf{pda} \) – Integer  
\textit{Input}

\textit{On entry}: the stride separating row or column elements (depending on the value of \textbf{order}) in the array \( \textbf{a} \).

\textit{Constraint}: \( \textbf{pda} \geq \max(1, \text{n}) \).

7: \( \textbf{ipiv}[\text{n}] \) – Integer  
\textit{Output}

\textit{On exit}: if \textbf{fail.code} = \text{NE\_NOERROR}, details of the interchanges and the block structure of \( D \), as determined by \texttt{nag\_dsytrf (f07mdc)}.

\textbf{ipiv}[k - 1] > 0
\begin{align*}
& \text{Rows and columns } k \text{ and } \textbf{ipiv}[k - 1] \text{ were interchanged, and } d_{kk} \text{ is a } 1 \times 1 \text{ diagonal block.}
\end{align*}

\textbf{uplo} = \text{Nag\_Upper} \text{ and } \textbf{ipiv}[k - 1] = \textbf{ipiv}[k - 2] < 0
\begin{align*}
& \text{Rows and columns } k - 1 \text{ and } -\textbf{ipiv}[k - 1] \text{ were interchanged and } d_{k-1,k,k-1,k} \text{ is a } 2 \times 2 \text{ diagonal block.}
\end{align*}

\textbf{uplo} = \text{Nag\_Lower} \text{ and } \textbf{ipiv}[k - 1] = \textbf{ipiv}[k] < 0
\begin{align*}
& \text{Rows and columns } k + 1 \text{ and } -\textbf{ipiv}[k - 1] \text{ were interchanged and } d_{k,k+1,k,k+1} \text{ is a } 2 \times 2 \text{ diagonal block.}
\end{align*}

8: \( \textbf{b}[\text{dim}] \) – double  
\textit{Input/Output}

\textit{Note}: the dimension, \( \text{dim} \), of the array \( \textbf{b} \) must be at least
\[
\max(1, \text{pdb} \times \text{nrhs}) \text{ when } \text{order} = \text{Nag\_ColMajor}; \\
\max(1, \text{n} \times \text{pdb}) \text{ when } \text{order} = \text{Nag\_RowMajor}.
\]

The \((i,j)\)th element of the matrix \( B \) is stored in
\[
\begin{align*}
\textbf{b}[ (j-1) \times \text{pdb} + i - 1 ] & \text{ when } \text{order} = \text{Nag\_ColMajor}; \\
\textbf{b}[ (i-1) \times \text{pdb} + j - 1 ] & \text{ when } \text{order} = \text{Nag\_RowMajor}.
\end{align*}
\]

\textit{On entry}: the \( n \) by \( r \) matrix of right-hand sides \( B \).

\textit{On exit}: if \textbf{fail.code} = \text{NE\_NOERROR} or \text{NE\_RCOND}, the \( n \) by \( r \) solution matrix \( X \).
9:  

\textbf{pdb} – Integer 

\textit{Input}

\textit{On entry}: the stride separating row or column elements (depending on the value of \textbf{order}) in the array \textbf{b}.

\textit{Constraints}:

- if \textbf{order} = Nag.ColMajor, \textbf{pdb} \geq \max(1, \textbf{n})
- if \textbf{order} = Nag.RowMajor, \textbf{pdb} \geq \max(1, \textbf{nrhs})

10:  

\textbf{rcond} – double *

\textit{Output}

\textit{On exit}: if no constraints are violated, an estimate of the reciprocal of the condition number of the matrix \textbf{A}, computed as \textbf{rcond} = 1/\left(\|A\|_1 \|A^{-1}\|_1\right)

11:  

\textbf{errbnd} – double *

\textit{Output}

\textit{On exit}: if \textbf{fail} = NE_NOERROR or NE_RCOND, an estimate of the forward error bound for a computed solution \(\hat{x}\), such that \(\|\hat{x} - x\|_1 / \|x\|_1 \leq \textbf{errbnd}\), where \(\hat{x}\) is a column of the computed solution returned in the array \textbf{b} and \(x\) is the corresponding column of the exact solution \(X\). If \textbf{rcond} is less than machine precision, then \textbf{errbnd} is returned as unity.

12:  

\textbf{fail} – NagError *

\textit{Input/Output}

The NAG error argument (see Section 3.6 in the Essential Introduction).

6  \textbf{Error Indicators and Warnings}

\textbf{NE_ALLOC_FAIL}

Dynamic memory allocation failed.
See Section 3.2.1.2 in the Essential Introduction for further information.

\textbf{NE_BAD_PARAM}

On entry, argument \textit{value} had an illegal value.

\textbf{NE_INT}

On entry, \textbf{n} = \textit{value}.
Constraint: \textbf{n} \geq 0.

On entry, \textbf{nrhs} = \textit{value}.
Constraint: \textbf{nrhs} \geq 0.

On entry, \textbf{pda} = \textit{value}.
Constraint: \textbf{pda} > 0.

On entry, \textbf{pdb} = \textit{value}.
Constraint: \textbf{pdb} > 0.

\textbf{NE_INT_2}

On entry, \textbf{pda} = \textit{value} and \textbf{n} = \textit{value}.
Constraint: \textbf{pda} \geq \max(1, \textbf{n}).

On entry, \textbf{pdb} = \textit{value} and \textbf{n} = \textit{value}.
Constraint: \textbf{pdb} \geq \max(1, \textbf{n}).

On entry, \textbf{pdb} = \textit{value} and \textbf{nrhs} = \textit{value}.
Constraint: \textbf{pdb} \geq \max(1, \textbf{nrhs}).
NE_INTERNAL_ERROR
An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.
An unexpected error has been triggered by this function. Please contact NAG. See Section 3.6.6 in the Essential Introduction for further information.

NE_NO_LICENCE
Your licence key may have expired or may not have been installed correctly. See Section 3.6.5 in the Essential Introduction for further information.

NE_RCOND
A solution has been computed, but rcond is less than machine precision so that the matrix A is numerically singular.

NE_SINGULAR
Diagonal block <value> of the block diagonal matrix is zero. The factorization has been completed, but the solution could not be computed.

7 Accuracy
The computed solution for a single right-hand side, \( \hat{x} \), satisfies an equation of the form
\[
(A + E)\hat{x} = b,
\]
where
\[
\|E\|_1 = O(\epsilon)\|A\|_1
\]
and \( \epsilon \) is the machine precision. An approximate error bound for the computed solution is given by
\[
\frac{\|\hat{x} - x\|_1}{\|x\|_1} \leq \kappa(A)\|E\|_1 / \|A\|_1,
\]
where \( \kappa(A) = \|A^{-1}\|_1\|A\|_1 \), the condition number of \( A \) with respect to the solution of the linear equations. nag_real_sym_lin_solve (f04bhc) uses the approximation \( \|E\|_1 = \epsilon\|A\|_1 \) to estimate errbnd. See Section 4.4 of Anderson et al. (1999) for further details.

8 Parallelism and Performance
nag_real_sym_lin_solve (f04bhc) is not threaded by NAG in any implementation.
nag_real_sym_lin_solve (f04bhc) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.
Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users’ Note for your implementation for any additional implementation-specific information.

9 Further Comments
The integer allocatable memory required is \( n \), and the double allocatable memory required is \( \text{max}(2 \times n, \text{iwork}) \), where \text{iwork} is the optimum workspace required by nag_dsysv (f07mac). If this failure occurs it may be possible to solve the equations by calling the packed storage version of nag_real_sym_lin_solve (f04bhc), nag_real_sym_packed_lin_solve (f04bjc), or by calling nag_dsysv (f07mac) directly with less than the optimum workspace (see Chapter f07).
The total number of floating-point operations required to solve the equations $AX = B$ is proportional to $(\frac{1}{3}n^3 + 2n^2r)$. The condition number estimation typically requires between four and five solves and never more than eleven solves, following the factorization.

In practice the condition number estimator is very reliable, but it can underestimate the true condition number; see Section 15.3 of Higham (2002) for further details.

The complex analogues of nag_real_sym_lin_solve (f04bhc) are nag_herm_lin_solve (f04chc) for complex Hermitian matrices, and nag_complex_sym_lin_solve (f04dhc) for complex symmetric matrices.

10 Example

This example solves the equations

$$AX = B,$$

where $A$ is the symmetric indefinite matrix

$$A = \begin{pmatrix} -1.81 & 2.06 & 0.63 & -1.15 \\ 2.06 & 1.15 & 1.87 & 4.20 \\ 0.63 & 1.87 & -0.21 & 3.87 \\ -1.15 & 4.20 & 3.87 & 2.07 \end{pmatrix} \quad \text{and} \quad B = \begin{pmatrix} 0.96 & 3.93 \\ 6.07 & 19.25 \\ 8.38 & 9.90 \\ 9.50 & 27.85 \end{pmatrix}.$$

An estimate of the condition number of $A$ and an approximate error bound for the computed solutions are also printed.
