1 Purpose

nag_herm_packed_lin_solve (f04cjc) computes the solution to a complex system of linear equations $AX = B$, where $A$ is an $n$ by $n$ complex Hermitian matrix, stored in packed format and $X$ and $B$ are $n$ by $r$ matrices. An estimate of the condition number of $A$ and an error bound for the computed solution are also returned.

2 Specification

```c
#include <nag.h>
#include <nagf04.h>
void nag_herm_packed_lin_solve (Nag_OrderType order, Nag_UploType uplo,
    Integer n, Integer nrhs, Complex ap[], Integer ipiv[], Complex b[],
    Integer pdb, double *rcond, double *errbnd, NagError *fail)
```

3 Description

The diagonal pivoting method is used to factor $A$ as $A = UDU^H$, if $uplo = Nag_{Upper}$, or $A = LDL^H$, if $uplo = Nag_{Lower}$, where $U$ (or $L$) is a product of permutation and unit upper (lower) triangular matrices, and $D$ is Hermitian and block diagonal with 1 by 1 and 2 by 2 diagonal blocks. The factored form of $A$ is then used to solve the system of equations $AX = B$.

4 References

5 Arguments

1:  
`order` – Nag_OrderType  
*Input*

*On entry:* the `order` argument specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by `order = Nag_RowMajor`. See Section 3.2.1.3 in the Essential Introduction for a more detailed explanation of the use of this argument.

*Constraint:* `order = Nag_RowMajor` or `Nag_ColMajor`.

2:  
`uplo` – Nag_UploType  
*Input*

*On entry:* if `uplo = Nag_Upper`, the upper triangle of the matrix $A$ is stored. If `uplo = Nag_Lower`, the lower triangle of the matrix $A$ is stored.

*Constraint:* `uplo = Nag_Upper` or `Nag_Lower`.

3:  
`n` – Integer  
*Input*

*On entry:* the number of linear equations $n$, i.e., the order of the matrix $A$.

*Constraint:* $n \geq 0$. 

Mark 25
4: \texttt{nrhs} – Integer

\textit{Input}

\textit{On entry:} the number of right-hand sides \(r\), i.e., the number of columns of the matrix \(B\).

\textit{Constraint:} \(\texttt{nrhs} \geq 0\).

5: \texttt{ap[dim]} – Complex

\textit{Input/Output}

\textit{Note:} the dimension, \(dim\), of the array \texttt{ap} must be at least \(\max(1, \text{n} \times (\text{n} + 1)/2)\).

\textit{On entry:} the \(n\) by \(n\) Hermitian matrix \(A\), packed column-wise in a linear array. The \(j\)th column of the matrix \(A\) is stored in the array \texttt{ap} as follows:

The storage of elements \(A_{ij}\) depends on the \texttt{order} and \texttt{uplo} arguments as follows:

if \(\texttt{order} = \text{Nag\_ColMajor}\) and \(\texttt{uplo} = \text{Nag\_Upper}\),

\(A_{ij}\) is stored in \(\texttt{ap}[(j - 1) \times j/2 + i - 1]\), for \(i \leq j\);

if \(\texttt{order} = \text{Nag\_ColMajor}\) and \(\texttt{uplo} = \text{Nag\_Lower}\),

\(A_{ij}\) is stored in \(\texttt{ap}[(2n - j) \times (j - 1)/2 + i - 1]\), for \(i \geq j\);

if \(\texttt{order} = \text{Nag\_RowMajor}\) and \(\texttt{uplo} = \text{Nag\_Upper}\),

\(A_{ij}\) is stored in \(\texttt{ap}[(2n - i) \times (i - 1)/2 + j - 1]\), for \(i \leq j\);

if \(\texttt{order} = \text{Nag\_RowMajor}\) and \(\texttt{uplo} = \text{Nag\_Lower}\),

\(A_{ij}\) is stored in \(\texttt{ap}[(i - 1) \times i/2 + j - 1]\), for \(i \geq j\).

\textit{On exit:} if \texttt{fail\_code} = \text{NE\_NOERROR}, the block diagonal matrix \(D\) and the multipliers used to obtain the factor \(U\) or \(L\) from the factorization \(A = UDU^H\) or \(A = LDL^H\) as computed by \texttt{nag\_zhptrf} (f07prc), stored as a packed triangular matrix in the same storage format as \(A\).

6: \texttt{ipiv[n]} – Integer

\textit{Output}

\textit{On exit:} if \texttt{fail\_code} = \text{NE\_NOERROR}, details of the interchanges and the block structure of \(D\), as determined by \texttt{nag\_zhptrf} (f07prc).

If \texttt{ipiv[k - 1]} \(> 0\), then rows and columns \(k\) and \texttt{ipiv[k - 1]} were interchanged, and \(d_{kk}\) is a 1 by 1 diagonal block;

if \(\texttt{uplo} = \text{Nag\_Upper}\) and \texttt{ipiv[k - 1]} = \texttt{ipiv[k - 2]} \(< 0\), then rows and columns \(k - 1\) and \(-\texttt{ipiv[k - 1]}\) were interchanged and \(d_{k-1,k-1,k-1,k}\) is a 2 by 2 diagonal block;

if \(\texttt{uplo} = \text{Nag\_Lower}\) and \texttt{ipiv[k - 1]} = \texttt{ipiv[k]} \(< 0\), then rows and columns \(k + 1\) and \(-\texttt{ipiv[k - 1]}\) were interchanged and \(d_{k+1,k,k+1,k+1}\) is a 2 by 2 diagonal block.

7: \texttt{b[dim]} – Complex

\textit{Input/Output}

\textit{Note:} the dimension, \(dim\), of the array \texttt{b} must be at least

\(\max(1, \text{pdb} \times \text{nrhs})\) when \texttt{order} = \text{Nag\_ColMajor};

\(\max(1, \text{n} \times \text{pdb})\) when \texttt{order} = \text{Nag\_RowMajor}.

The \((i, j)\)th element of the matrix \(B\) is stored in

\(\texttt{b}[(j - 1) \times \text{pdb} + i - 1]\) when \texttt{order} = \text{Nag\_ColMajor};

\(\texttt{b}[(i - 1) \times \text{pdb} + j - 1]\) when \texttt{order} = \text{Nag\_RowMajor}.

\textit{On entry:} the \(n\) by \(r\) matrix of right-hand sides \(B\).

\textit{On exit:} if \texttt{fail\_code} = \text{NE\_NOERROR} or \text{NE\_RCOND}, the \(n\) by \(r\) solution matrix \(X\).

8: \texttt{pdb} – Integer

\textit{Input}

\textit{On entry:} the stride separating row or column elements (depending on the value of \texttt{order}) in the array \texttt{b}.

\textit{Constraints:}

if \texttt{order} = \text{Nag\_ColMajor}, \texttt{pdb} \(\geq \max(1, \text{n})\);

if \texttt{order} = \text{Nag\_RowMajor}, \texttt{pdb} \(\geq \max(1, \text{nrhs})\).
9:  \textbf{rcond} – double * \hspace{1cm} Output

\textit{On exit:} if no constraints are violated, an estimate of the reciprocal of the condition number of the matrix \( A \), computed as 
\[
\text{rcond} = 1 / \left( \| A \|_1 \| A^{-1} \|_1 \right).
\]

10:  \textbf{errbnd} – double * \hspace{1cm} Output

\textit{On exit:} if \texttt{fail.code} = NE_NOERROR or NE_RCOND, an estimate of the forward error bound for a computed solution \( \hat{x} \), such that 
\[
\| \hat{x} - x \|_1 / \| x \|_1 \leq \text{errbnd},
\]
where \( \hat{x} \) is a column of the computed solution returned in the array \( b \) and \( x \) is the corresponding column of the exact solution \( X \). If \text{rcond} is less than \textit{machine precision}, then \text{errbnd} is returned as unity.

11:  \textbf{fail} – NagError * \hspace{1cm} Input/Output

The NAG error argument (see Section 3.6 in the Essential Introduction).

6 \ Error Indicators and Warnings

\textbf{NE_ALLOC_FAIL}

Dynamic memory allocation failed.

See Section 3.2.1.2 in the Essential Introduction for further information.

\textbf{NE_BAD_PARAM}

On entry, argument \langle value \rangle had an illegal value.

\textbf{NE_INT}

On entry, \( n = \langle \text{value} \rangle \).

Constraint: \( n \geq 0 \).

On entry, \( nrhs = \langle \text{value} \rangle \).

Constraint: \( nrhs \geq 0 \).

On entry, \( pdb = \langle \text{value} \rangle \).

Constraint: \( pdb > 0 \).

\textbf{NE_INTERNAL_ERROR}

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.

An unexpected error has been triggered by this function. Please contact NAG.

See Section 3.6.6 in the Essential Introduction for further information.

\textbf{NE_NO_LICENCE}

Your licence key may have expired or may not have been installed correctly.

See Section 3.6.5 in the Essential Introduction for further information.

\textbf{NE_RCOND}

A solution has been computed, but \textbf{rcond} is less than \textit{machine precision} so that the matrix \( A \) is numerically singular.
NE_SINGULAR

Diagonal block \( \langle \text{value} \rangle \) of the block diagonal matrix is zero. The factorization has been completed, but the solution could not be computed.

7 Accuracy

The computed solution for a single right-hand side, \( \hat{x} \), satisfies an equation of the form

\[
(A + E)\hat{x} = b,
\]

where

\[
\|E\|_1 = O(\epsilon)\|A\|_1
\]

and \( \epsilon \) is the machine precision. An approximate error bound for the computed solution is given by

\[
\frac{\|\hat{x} - x\|_1}{\|x\|_1} \leq \kappa(A)\frac{\|E\|_1}{\|A\|_1},
\]

where \( \kappa(A) = \|A^{-1}\|_1\|A\|_1 \), the condition number of \( A \) with respect to the solution of the linear equations. nag_herm_packed_lin_solve (f04cjc) uses the approximation \( \|E\|_1 = \epsilon\|A\|_1 \) to estimate errbnd. See Section 4.4 of Anderson et al. (1999) for further details.

8 Parallelism and Performance

nag_herm_packed_lin_solve (f04cjc) is not threaded by NAG in any implementation. nag_herm_packed_lin_solve (f04cjc) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users’ Note for your implementation for any additional implementation-specific information.

9 Further Comments

The packed storage scheme is illustrated by the following example when \( n = 4 \) and uplo = Nag_Upper.

Two-dimensional storage of the Hermitian matrix \( A \):

\[
\begin{array}{cccc}
  a_{11} & a_{12} & a_{13} & a_{14} \\
  a_{22} & a_{23} & a_{24} & \\
  a_{33} & a_{34} & & \\
  a_{44} & & & \\
\end{array}
\]

Packed storage of the upper triangle of \( A \):

\[
ap = [a_{11}, a_{12}, a_{22}, a_{13}, a_{23}, a_{14}, a_{33}, a_{24}, a_{34}, a_{44}].
\]

The total number of floating-point operations required to solve the equations \( AX = B \) is proportional to \( \left( \frac{1}{2}n^3 + 2n^2r \right) \). The condition number estimation typically requires between four and five solves and never more than eleven solves, following the factorization.

In practice the condition number estimator is very reliable, but it can underestimate the true condition number; see Section 15.3 of Higham (2002) for further details.

Function nag_complex_sym_packed_lin_solve (f04dj) is for complex symmetric matrices, and the real analogue of nag_herm_packed_lin_solve (f04cjc) is nag_real_sym_packed_lin_solve (f04bjc).
10  Example

This example solves the equations

\[ AX = B, \]

where \( A \) is the Hermitian indefinite matrix

\[
\begin{pmatrix}
  -1.84 & 0.11 - 0.11i & -1.78 - 1.18i & 3.91 - 1.50i \\
  0.11 + 0.11i & -4.63 & -1.84 + 0.03i & 2.21 + 0.21i \\
  -1.78 + 1.18i & -1.84 - 0.03i & -8.87 & 1.58 - 0.90i \\
  3.91 + 1.50i & 2.21 - 0.21i & 1.58 + 0.90i & -1.36
\end{pmatrix}
\]

and

\[
\begin{pmatrix}
  2.98 - 10.18i & 28.68 - 39.89i \\
  -9.58 + 3.88i & -24.79 - 8.40i \\
  -0.77 - 16.05i & 4.23 - 70.02i \\
  7.79 + 5.48i & -35.39 + 18.01i
\end{pmatrix}
\]

An estimate of the condition number of \( A \) and an approximate error bound for the computed solutions are also printed.
