NAG Library Function Document

**nag_dgtrfs (f07chc)**

1 Purpose

nag_dgtrfs (f07chc) computes error bounds and refines the solution to a real system of linear equations $AX = B$ or $A^T X = B$, where $A$ is an $n$ by $n$ tridiagonal matrix and $X$ and $B$ are $n$ by $r$ matrices, using the $LU$ factorization returned by nag_dgttrf (f07cdc) and an initial solution returned by nag_dgttrs (f07cec). Iterative refinement is used to reduce the backward error as much as possible.

2 Specification

```c
#include <nag.h>
#include <nagf07.h>
void nag_dgtrfs (Nag_OrderType order, Nag_TransType trans, Integer n, Integer nrhs, const double dl[], const double d[], const double du[], const double dlf[], const double df[], const double duf[], const double du2[], const Integer ipiv[], const double b[], Integer pdb, double x[], Integer pdx, double ferr[], double berr[], NagError *fail)
```

3 Description

nag_dgtrfs (f07chc) should normally be preceded by calls to nag_dgttrf (f07cdc) and nag_dgttrs (f07cec). nag_dgttrf (f07cdc) uses Gaussian elimination with partial pivoting and row interchanges to factorize the matrix $A$ as

$$A = PLU,$$

where $P$ is a permutation matrix, $L$ is unit lower triangular with at most one nonzero subdiagonal element in each column, and $U$ is an upper triangular band matrix, with two superdiagonals. nag_dgttrs (f07cec) then utilizes the factorization to compute a solution, $\hat{X}$, to the required equations. Letting $\hat{x}$ denote a column of $\hat{X}$, nag_dgtrfs (f07chc) computes a component-wise backward error, $\beta$, the smallest relative perturbation in each element of $A$ and $b$ such that $\hat{x}$ is the exact solution of a perturbed system

$$(A + E)\hat{x} = b + f,$$

with $|e_{ij}| \leq \beta |a_{ij}|$, and $|f_j| \leq \beta |b_j|$.

The function also estimates a bound for the component-wise forward error in the computed solution defined by $\max|x_i - \hat{x}_i|/\max|\hat{x}_i|$, where $x$ is the corresponding column of the exact solution, $X$.

4 References

5 Arguments

1. **order – Nag_OrderType**  
   
   **Input**  
   
   On entry: the order argument specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by order = Nag_RowMajor. See Section 3.2.1.3 in the Essential Introduction for a more detailed explanation of the use of this argument.

   **Constraint:** order = Nag_RowMajor or Nag_ColMajor.
**trans** – Nag_TransType

*On entry:* specifies the equations to be solved as follows:

- **trans** = Nag_NoTrans
  - Solve $AX = B$ for $X$.
- **trans** = Nag_Trans or Nag_ConjTrans
  - Solve $A^TX = B$ for $X$.

*Constraint:* **trans** = Nag_NoTrans, Nag_Trans or Nag_ConjTrans.

**n** – Integer

*On entry:* $n$, the order of the matrix $A$.

*Constraint:* $n \geq 0$.

**nrhs** – Integer

*On entry:* $r$, the number of right-hand sides, i.e., the number of columns of the matrix $B$.

*Constraint:* $\text{nrhs} \geq 0$.

**dl[dim]** – const double

*Note:* the dimension, $\text{dim}$, of the array $\text{dl}$ must be at least $\text{max}(1,n-1)$.

*On entry:* must contain the $(n-1)$ subdiagonal elements of the matrix $A$.

**d[dim]** – const double

*Note:* the dimension, $\text{dim}$, of the array $\text{d}$ must be at least $\text{max}(1,n)$.

*On entry:* must contain the $n$ diagonal elements of the matrix $A$.

**du[dim]** – const double

*Note:* the dimension, $\text{dim}$, of the array $\text{du}$ must be at least $\text{max}(1,n-1)$.

*On entry:* must contain the $(n-1)$ superdiagonal elements of the matrix $A$.

**dlf[dim]** – const double

*Note:* the dimension, $\text{dim}$, of the array $\text{dlf}$ must be at least $\text{max}(1,n-1)$.

*On entry:* must contain the $(n-1)$ multipliers that define the matrix $L$ of the $LU$ factorization of $A$.

**df[dim]** – const double

*Note:* the dimension, $\text{dim}$, of the array $\text{df}$ must be at least $\text{max}(1,n)$.

*On entry:* must contain the $n$ diagonal elements of the upper triangular matrix $U$ from the $LU$ factorization of $A$.

**duf[dim]** – const double

*Note:* the dimension, $\text{dim}$, of the array $\text{duf}$ must be at least $\text{max}(1,n-1)$.

*On entry:* must contain the $(n-1)$ elements of the first superdiagonal of $U$.

**du2[dim]** – const double

*Note:* the dimension, $\text{dim}$, of the array $\text{du2}$ must be at least $\text{max}(1,n-2)$.

*On entry:* must contain the $(n-2)$ elements of the second superdiagonal of $U$. 
12: ipiv[\text{dim}] – const Integer  
   \text{Input} 
   \text{Note:} the dimension, \text{dim}, of the array ipiv must be at least \text{max}(1, n). 
   \text{On entry:} must contain the \text{n} pivot indices that define the permutation matrix \text{P}. At the \text{i}th step, 
   row \text{i} of the matrix was interchanged with row \text{ipiv}[i - 1], and \text{ipiv}[i - 1] must always be either \text{i} or 
   (\text{i} + 1), \text{ipiv}[i - 1] = \text{i} indicating that a row interchange was not performed. 

13: b[\text{dim}] – const double  
   \text{Input} 
   \text{Note:} the dimension, \text{dim}, of the array b must be at least \text{max}(1, \text{pdb} \times \text{nrhs}) when \text{order} = \text{Nag\_ColMajor}; \text{max}(1, \text{n} \times \text{pdb}) when \text{order} = \text{Nag\_RowMajor}. 
   \text{On entry:} the \text{n} by \text{r} matrix of right-hand sides \text{B}. 

14: pdb – Integer  
   \text{Input} 
   \text{On entry:} the stride separating row or column elements (depending on the value of \text{order}) in the 
   array b. 
   \text{Constraints:} 
   \begin{align*} 
   \text{if} \ \text{order} = \text{Nag\_ColMajor}, & \ \text{pdb} \geq \text{max}(1, \text{n}); \\ 
   \text{if} \ \text{order} = \text{Nag\_RowMajor}, & \ \text{pdb} \geq \text{max}(1, \text{nrhs}). 
   \end{align*} 

15: x[\text{dim}] – double  
   \text{Input/Output} 
   \text{Note:} the dimension, \text{dim}, of the array x must be at least \text{max}(1, \text{pdx} \times \text{nrhs}) when \text{order} = \text{Nag\_ColMajor}; \text{max}(1, \text{n} \times \text{pdx}) when \text{order} = \text{Nag\_RowMajor}. 
   \text{On entry:} the \text{n} by \text{r} initial solution matrix \text{X}. 
   \text{On exit:} the \text{n} by \text{r} refined solution matrix \text{X}. 

16: pdx – Integer  
   \text{Input} 
   \text{On entry:} the stride separating row or column elements (depending on the value of \text{order}) in the 
   array x. 
   \text{Constraints:} 
   \begin{align*} 
   \text{if} \ \text{order} = \text{Nag\_ColMajor}, & \ \text{pdx} \geq \text{max}(1, \text{n}); \\ 
   \text{if} \ \text{order} = \text{Nag\_RowMajor}, & \ \text{pdx} \geq \text{max}(1, \text{nrhs}). 
   \end{align*} 

17: ferr[\text{nrhs}] – double  
   \text{Output} 
   \text{On exit:} estimate of the forward error bound for each computed solution vector, such that 
   \begin{align*} 
   \left\| \hat{x}_j - x_j \right\|_\infty / \left\| \hat{x}_j \right\|_\infty \leq \text{ferr}[j - 1], \end{align*} 
   where \hat{x}_j is the \text{j}th column of the computed solution returned in 
   the array \text{x} and \text{x}_j is the corresponding column of the exact solution \text{X}. The estimate is almost 
   always a slight overestimate of the true error.
18: berr[nrhs] – double

Output

On exit: estimate of the component-wise relative backward error of each computed solution vector
\(\hat{x}_j\) (i.e., the smallest relative change in any element of \(A\) or \(B\) that makes \(\hat{x}_j\) an exact solution).

19: fail – NagError *

Input/Output

The NAG error argument (see Section 3.6 in the Essential Introduction).

6 Error Indicators and Warnings

NE_ALLOC_FAIL

Dynamic memory allocation failed.
See Section 3.2.1.2 in the Essential Introduction for further information.

NE_BAD_PARAM

On entry, argument \langle value\rangle had an illegal value.

NE_INT

On entry, \(n = \langle value\rangle\).
Constraint: \(n \geq 0\).

On entry, \(nrhs = \langle value\rangle\).
Constraint: \(nrhs \geq 0\).

On entry, \(pdb = \langle value\rangle\).
Constraint: \(pdb > 0\).

On entry, \(pdx = \langle value\rangle\).
Constraint: \(pdx > 0\).

NE_INT_2

On entry, \(pdx = \langle value\rangle\) and \(n = \langle value\rangle\).
Constraint: \(pdx \geq \max(1, n)\).

On entry, \(pdx = \langle value\rangle\) and \(nrhs = \langle value\rangle\).
Constraint: \(pdx \geq \max(1, nrhs)\).

On entry, \(pdx = \langle value\rangle\) and \(n = \langle value\rangle\).
Constraint: \(pdx \geq \max(1, n)\).

On entry, \(pdx = \langle value\rangle\) and \(nrhs = \langle value\rangle\).
Constraint: \(pdx \geq \max(1, nrhs)\).

NE_INTERNAL_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the
call is correct then please contact NAG for assistance.

An unexpected error has been triggered by this function. Please contact NAG.
See Section 3.6.6 in the Essential Introduction for further information.

NE_NO_LICENCE

Your licence key may have expired or may not have been installed correctly.
See Section 3.6.5 in the Essential Introduction for further information.
7 Accuracy

The computed solution for a single right-hand side, \( \hat{x} \), satisfies an equation of the form

\[
(A + E)\hat{x} = b,
\]

where

\[
\|E\|_\infty = O(\epsilon)\|A\|_\infty
\]

and \( \epsilon \) is the machine precision. An approximate error bound for the computed solution is given by

\[
\frac{\|\hat{x} - x\|_\infty}{\|x\|_\infty} \leq \kappa(A)\frac{\|E\|_\infty}{\|A\|_\infty},
\]

where \( \kappa(A) = \|A^{-1}\|_\infty \|A\|_\infty \), the condition number of \( A \) with respect to the solution of the linear equations. See Section 4.4 of Anderson et al. (1999) for further details.

Function nag_dgtrfs (f07chc) can be used to estimate the condition number of \( A \).

8 Parallelism and Performance

nag_dgtrfs (f07chc) is threaded by NAG for parallel execution in multithreaded implementations of the NAG Library.

nag_dgtrfs (f07chc) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users’ Note for your implementation for any additional implementation-specific information.

9 Further Comments

The total number of floating-point operations required to solve the equations \( AX = B \) or \( A^T X = B \) is proportional to \( nr \). At most five steps of iterative refinement are performed, but usually only one or two steps are required.

The complex analogue of this function is nag_zgtrfs (f07cvc).

10 Example

This example solves the equations

\[
AX = B,
\]

where \( A \) is the tridiagonal matrix

\[
A = \begin{pmatrix}
3.0 & 2.1 & 0 & 0 & 0 \\
3.4 & 2.3 & -1.0 & 0 & 0 \\
0 & 3.6 & -5.0 & 1.9 & 0 \\
0 & 0 & 7.0 & -0.9 & 8.0 \\
0 & 0 & 0 & -6.0 & 7.1 \\
\end{pmatrix}
\]

and \( B = \begin{pmatrix}
2.7 & 6.6 \\
-0.5 & 10.8 \\
2.6 & -3.2 \\
0.6 & -11.2 \\
2.7 & 19.1 \\
\end{pmatrix} \).

Estimates for the backward errors and forward errors are also output.
