NAG Library Function Document

nag_dtpqrt (f08bbc)

1 Purpose

nag_dtpqrt (f08bbc) computes the QR factorization of a real \((m + n)\) by \(n\) triangular-pentagonal matrix.

2 Specification

```c
#include <nag.h>
#include <nagf08.h>

void nag_dtpqrt (Nag_OrderType order, Integer m, Integer n, Integer l,
                  Integer nb, double a[], Integer pda, double b[], Integer pdb,
                  double t[], Integer pdt, NagError *fail)
```

3 Description

nag_dtpqrt (f08bbc) forms the QR factorization of a real \((m + n)\) by \(n\) triangular-pentagonal matrix \(C\),

\[
C = \begin{pmatrix} A \\ B \end{pmatrix}
\]

where \(A\) is an upper triangular \(n\) by \(n\) matrix and \(B\) is an \(m\) by \(n\) pentagonal matrix consisting of an \((m - l)\) by \(n\) rectangular matrix \(B_1\) on top of an \(l\) by \(n\) upper trapezoidal matrix \(B_2\):

\[
B = \begin{pmatrix} B_1 \\ B_2 \end{pmatrix}
\]

The upper trapezoidal matrix \(B_2\) consists of the first \(l\) rows of an \(n\) by \(n\) upper triangular matrix, where \(0 \leq l \leq \min(m, n)\). If \(l = 0\), \(B\) is \(m\) by \(n\) rectangular; if \(l = n\) and \(m = n\), \(B\) is upper triangular.

A recursive, explicitly blocked, QR factorization (see nag_dgeqrt (f08abc)) is performed on the matrix \(C\). The upper triangular matrix \(R\), details of the orthogonal matrix \(Q\), and further details (the block reflector factors) of \(Q\) are returned.

Typically the matrix \(A\) or \(B_2\) contains the matrix \(R\) from the QR factorization of a subproblem and nag_dtpqrt (f08bbc) performs the QR update operation from the inclusion of matrix \(B_1\).

For example, consider the QR factorization of an \(l\) by \(n\) matrix \(\tilde{B}\) with \(l < n\): \(\tilde{B} = Q\tilde{R} = (\tilde{R}_1 \ \tilde{R}_2)\), where \(\tilde{R}_1\) is \(l\) by \(l\) upper triangular and \(\tilde{R}_2\) is \((n - l)\) by \(n\) rectangular (this can be performed by nag_dgeqrt (f08abc)). Given an initial least-squares problem \(\tilde{B}\tilde{X} = \tilde{Y}\) where \(X\) and \(Y\) are \(l\) by \(n_{rhs}\) matrices, we have \(\tilde{R}\tilde{X} = \tilde{Q}^T\tilde{Y}\).

Now, adding an additional \(m - l\) rows to the original system gives the augmented least squares problem

\[
BX = Y
\]

where \(B\) is an \(m\) by \(n\) matrix formed by adding \(m - l\) rows on top of \(\tilde{R}\) and \(Y\) is an \(m\) by \(n_{rhs}\) matrix formed by adding \(m - l\) rows on top of \(\tilde{Q}^T\tilde{Y}\).

nag_dtpqrt (f08bbc) can then be used to perform the QR factorization of the pentagonal matrix \(B\); the \(n\) by \(n\) matrix \(A\) will be zero on input and contain \(\tilde{R}\) on output.

In the case where \(\tilde{B}\) is \(r\) by \(n\), \(r \geq n\), \(\tilde{R}\) is \(n\) by \(n\) upper triangular (forming \(A\)) on top of \(r - n\) rows of zeros (forming first \(r - n\) rows of \(B\)). Augmentation is then performed by adding rows to the bottom of \(B\) with \(l = 0\).
4 References

5 Arguments
1: order – Nag_OrderType
   On entry: the order argument specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by order = Nag_RowMajor. See Section 3.2.1.3 in the Essential Introduction for a more detailed explanation of the use of this argument.
   Constraint: order = Nag_RowMajor or Nag_ColMajor.

2: m – Integer
   On entry: m, the number of rows of the matrix B.
   Constraint: m ≥ 0.

3: n – Integer
   On entry: n, the number of columns of the matrix B and the order of the upper triangular matrix A.
   Constraint: n ≥ 0.

4: l – Integer
   On entry: l, the number of rows of the trapezoidal part of B (i.e., B2).
   Constraint: 0 ≤ l ≤ min(m, n).

5: nb – Integer
   On entry: the explicitly chosen block-size to be used in the algorithm for computing the QR factorization. See Section 9 for details.
   Constraints:
   \[ nb \geq 1; \]
   if \( n > 0 \), \( nb \leq n \).

6: a[dim] – double
   Note: the dimension, dim, of the array a must be at least max(1, pda × n).
   The \((i, j)\)th element of the matrix A is stored in
   \[ a[(j - 1) \times pda + i - 1] \text{ when order = Nag_ColMajor}; \]
   \[ a[(i - 1) \times pda + j - 1] \text{ when order = Nag_RowMajor}. \]
   On entry: the n by n upper triangular matrix A.
   On exit: the upper triangle is overwritten by the corresponding elements of the n by n upper triangular matrix R.
7: \textbf{pda} -- Integer  
\textit{Input}

\textit{On entry:} the stride separating row or column elements (depending on the value of \textbf{order}) in the array \textit{a}.

\textit{Constraint:} \textbf{pda} \geq \max(1, n).

8: \textbf{b}[\textit{dim}] -- double  
\textit{Input/Output}

\textit{Note:} the dimension, \textit{dim}, of the array \textit{b} must be at least

\begin{align*}
\max(1, \textbf{pdb} \times n) & \text{ when } \textbf{order} = \text{Nag\_ColMajor}; \\
\max(1, m \times \textbf{pdb}) & \text{ when } \textbf{order} = \text{Nag\_RowMajor}.
\end{align*}

The \((i, j)\)th element of the matrix \(B\) is stored in

\begin{align*}
\textbf{b}[(j - 1) \times \textbf{pdb} + i - 1] & \text{ when } \textbf{order} = \text{Nag\_ColMajor}; \\
\textbf{b}[(i - 1) \times \textbf{pdb} + j - 1] & \text{ when } \textbf{order} = \text{Nag\_RowMajor}.
\end{align*}

\textit{On entry:} the \(m\) by \(n\) pentagonal matrix \(B\) composed of an \((m - l)\) by \(n\) rectangular matrix \(B_1\) above an \(l\) by \(n\) upper trapezoidal matrix \(B_2\).

\textit{On exit:} details of the orthogonal matrix \(Q\).

9: \textbf{pdb} -- Integer  
\textit{Input}

\textit{On entry:} the stride separating row or column elements (depending on the value of \textbf{order}) in the array \textit{b}.

\textit{Constraints:}

\begin{align*}
\text{if } \textbf{order} = \text{Nag\_ColMajor}, & \quad \textbf{pdb} \geq \max(1, m); \\
\text{if } \textbf{order} = \text{Nag\_RowMajor}, & \quad \textbf{pdb} \geq \max(1, n).
\end{align*}

10: \textbf{t}[\textit{dim}] -- double  
\textit{Output}

\textit{Note:} the dimension, \textit{dim}, of the array \textit{t} must be at least

\begin{align*}
\max(1, \textbf{pdt} \times n) & \text{ when } \textbf{order} = \text{Nag\_ColMajor}; \\
\max(1, \textbf{nb} \times \textbf{pdt}) & \text{ when } \textbf{order} = \text{Nag\_RowMajor}.
\end{align*}

The \((i, j)\)th element of the matrix \(T\) is stored in

\begin{align*}
\textbf{t}[(j - 1) \times \textbf{pdt} + i - 1] & \text{ when } \textbf{order} = \text{Nag\_ColMajor}; \\
\textbf{t}[(i - 1) \times \textbf{pdt} + j - 1] & \text{ when } \textbf{order} = \text{Nag\_RowMajor}.
\end{align*}

\textit{On exit:} further details of the orthogonal matrix \(Q\). The number of blocks is \(b = \left\lfloor \frac{k}{\text{nb}} \right\rfloor\), where \(k = \min(m, n)\) and each block is of order \(\text{nb}\) except for the last block, which is of order \((k - (b - 1) \times \text{nb})\). For each of the blocks, an upper triangular block reflector factor is computed: \(T_1, T_2, \ldots, T_b\). These are stored in the \textbf{nb} by \(n\) matrix \(T\) as \(T = [T_1|T_2|\ldots|T_b]\).

11: \textbf{pdt} -- Integer  
\textit{Input}

\textit{On entry:} the stride separating row or column elements (depending on the value of \textbf{order}) in the array \textit{t}.

\textit{Constraints:}

\begin{align*}
\text{if } \textbf{order} = \text{Nag\_ColMajor}, & \quad \textbf{pdt} \geq \text{nb}; \\
\text{if } \textbf{order} = \text{Nag\_RowMajor}, & \quad \textbf{pdt} \geq \text{n}.
\end{align*}

12: \textbf{fail} -- NagError*  
\textit{Input/Output}

The NAG error argument (see Section 3.6 in the Essential Introduction).
6 Error Indicators and Warnings

**NE_ALLOC_FAIL**
Dynamic memory allocation failed.
See Section 3.2.1.2 in the Essential Introduction for further information.

**NE_BAD_PARAM**
On entry, argument <value> had an illegal value.

**NE_INT**
On entry, \( m = \langle \text{value} \rangle \).
Constraint: \( m \geq 0 \).
On entry, \( n = \langle \text{value} \rangle \).
Constraint: \( n \geq 0 \).

**NE_INT_2**
On entry, \( nb = \langle \text{value} \rangle \) and \( n = \langle \text{value} \rangle \).
Constraint: \( nb \geq 1 \) and if \( n > 0 \), \( nb \leq n \).
On entry, \( pda = \langle \text{value} \rangle \) and \( n = \langle \text{value} \rangle \).
Constraint: \( pda \geq \max(1, n) \).
On entry, \( pdb = \langle \text{value} \rangle \) and \( m = \langle \text{value} \rangle \).
Constraint: \( pdb \geq \max(1, m) \).
On entry, \( pdb = \langle \text{value} \rangle \) and \( n = \langle \text{value} \rangle \).
Constraint: \( pdb \geq \max(1, n) \).
On entry, \( pdt = \langle \text{value} \rangle \) and \( n = \langle \text{value} \rangle \).
Constraint: \( pdt \geq n \).
On entry, \( pdt = \langle \text{value} \rangle \) and \( nb = \langle \text{value} \rangle \).
Constraint: \( pdt \geq nb \).

**NE_INT_3**
On entry, \( l = \langle \text{value} \rangle \), \( m = \langle \text{value} \rangle \) and \( n = \langle \text{value} \rangle \).
Constraint: \( 0 \leq l \leq \min(m, n) \).

**NE_INTERNAL_ERROR**
An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.
An unexpected error has been triggered by this function. Please contact NAG.
See Section 3.6.6 in the Essential Introduction for further information.

**NE_NO_LICENCE**
Your licence key may have expired or may not have been installed correctly.
See Section 3.6.5 in the Essential Introduction for further information.

7 Accuracy
The computed factorization is the exact factorization of a nearby matrix \((A + E)\), where
\[
\|E\|_2 = O(\epsilon)\|A\|_2,
\]
and \( \epsilon \) is the machine precision.
8 Parallelism and Performance

nag_dtpqrt (f08bbc) is not threaded by NAG in any implementation.

nag_dtpqrt (f08bbc) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users’ Note for your implementation for any additional implementation-specific information.

9 Further Comments

The total number of floating-point operations is approximately \( \frac{2}{3}n^2(3m - n) \) if \( m \geq n \) or \( \frac{2}{3}m^2(3n - m) \) if \( m < n \).

The block size, \( nb \), used by nag_dtpqrt (f08bbc) is supplied explicitly through the interface. For moderate and large sizes of matrix, the block size can have a marked effect on the efficiency of the algorithm with the optimal value being dependent on problem size and platform. A value of \( nb = 64 \leq \min(m, n) \) is likely to achieve good efficiency and it is unlikely that an optimal value would exceed 340.

To apply \( Q \) to an arbitrary real rectangular matrix \( C \), nag_dtpqrt (f08bbc) may be followed by a call to nag_dtpmqrt (f08bcc). For example,

\[
\text{nag_dtpmqrt(Nag_ColMajor,Nag_LeftSide,Nag_Trans,m,p,n,l,nb,b,pdb,}
\text{t,pdt,c,pdc,&c(n+1,1),ldc,&fail)}
\]

forms \( C = Q^T C \), where \( C \) is \((m + n) \times p\).

To form the orthogonal matrix \( Q \) explicitly set \( p = m + n \), initialize \( C \) to the identity matrix and make a call to nag_dtpmqrt (f08bcc) as above.

10 Example

This example finds the basic solutions for the linear least squares problems

\[
\min \| Ax_i - b_i \|_2, \quad i = 1, 2
\]

where \( b_1 \) and \( b_2 \) are the columns of the matrix \( B \),

\[
A = \begin{pmatrix}
-0.57 & -1.28 & -0.39 & 0.25 \\
-1.93 & 1.08 & -0.31 & -2.14 \\
2.30 & 0.24 & 0.40 & -0.35 \\
-1.93 & 0.64 & -0.66 & 0.08 \\
0.15 & 0.30 & 0.15 & -2.13 \\
-0.02 & 1.03 & -1.43 & 0.50
\end{pmatrix}
\quad \text{and} \quad
B = \begin{pmatrix}
-2.67 & 0.41 \\
-0.55 & -3.10 \\
3.34 & -4.01 \\
-0.77 & 2.76 \\
0.48 & -6.17 \\
4.10 & 0.21
\end{pmatrix}.
\]

A \( QR \) factorization is performed on the first 4 rows of \( A \) using nag_dgeqrt (f08abc) after which the first 4 rows of \( B \) are updated by applying \( Q^T \) using nag_dgqmrt (f08acc). The remaining row is added by performing a \( QR \) update using nag_dtpqrt (f08bbc); \( B \) is updated by applying the new \( Q^T \) using nag_dtpmqrt (f08bcc); the solution is finally obtained by triangular solve using \( R \) from the updated \( QR \).
