NAG Library Function Document

nag_zhseqr (f08psc)

1 Purpose

nag_zhseqr (f08psc) computes all the eigenvalues and, optionally, the Schur factorization of a complex Hessenberg matrix or a complex general matrix which has been reduced to Hessenberg form.

2 Specification

```c
#include <nag.h>
#include <nagf08.h>

void nag_zhseqr (Nag_OrderType order, Nag_JobType job,
        Nag_ComputeZType compz, Integer n, Integer ilo, Integer ihi,
        Complex h[], Integer pdh, Complex w[], Complex z[], Integer pdz,
        NagError *fail)
```

3 Description

nag_zhseqr (f08psc) computes all the eigenvalues and, optionally, the Schur factorization of a complex upper Hessenberg matrix $H$:

$$H = ZTZ^H,$$

where $T$ is an upper triangular matrix (the Schur form of $H$), and $Z$ is the unitary matrix whose columns are the Schur vectors $z_i$. The diagonal elements of $T$ are the eigenvalues of $H$.

The function may also be used to compute the Schur factorization of a complex general matrix $A$ which has been reduced to upper Hessenberg form $H$:

$$A = QHQ^H \text{, where } Q \text{ is unitary},$$

$$= (QZ)T(QZ)^H.$$

In this case, after nag_zgehrd (f08nsc) has been called to reduce $A$ to Hessenberg form, nag_zunghr (f08ntc) must be called to form $Q$ explicitly; $Q$ is then passed to nag_zhseqr (f08psc), which must be called with compz = Nag_UpdateZ.

The function can also take advantage of a previous call to nag_zgebal (f08nvc) which may have balanced the original matrix before reducing it to Hessenberg form, so that the Hessenberg matrix $H$ has the structure:

$$\begin{pmatrix}
H_{11} & H_{12} & H_{13} \\
H_{21} & H_{22} & H_{23} \\
0 & H_{32} & H_{33}
\end{pmatrix}$$

where $H_{11}$ and $H_{33}$ are upper triangular. If so, only the central diagonal block $H_{22}$ (in rows and columns $i_{lo}$ to $i_{hi}$) needs to be further reduced to Schur form (the blocks $H_{12}$ and $H_{23}$ are also affected). Therefore the values of $i_{lo}$ and $i_{hi}$ can be supplied to nag_zhseqr (f08psc) directly. Also, nag_zgebak (f08nwc) must be called after this function to permute the Schur vectors of the balanced matrix to those of the original matrix. If nag_zgebal (f08nvc) has not been called however, then $i_{lo}$ must be set to 1 and $i_{hi}$ to $n$. Note that if the Schur factorization of $A$ is required, nag_zgebal (f08nvc) must not be called with job = Nag_Scale or Nag_DoBoth, because the balancing transformation is not unitary.

nag_zhseqr (f08psc) uses a multishift form of the upper Hessenberg QR algorithm, due to Bai and Demmel (1989). The Schur vectors are normalized so that $\|z_i\|_2 = 1$, but are determined only to within a complex factor of absolute value 1.
4 References

5 Arguments

1: order – Nag_OrderType
   
   On entry: the order argument specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by order = Nag_RowMajor. See Section 3.2.1.3 in the Essential Introduction for a more detailed explanation of the use of this argument.
   
   Constraint: order = Nag_RowMajor or Nag_ColMajor.

2: job – Nag_JobType
   
   On entry: indicates whether eigenvalues only or the Schur form T is required.
   
   job = Nag_EigVals
       Eigenvalues only are required.
   
   job = Nag_Schur
       The Schur form T is required.
   
   Constraint: job = Nag_EigVals or Nag_Schur.

3: compz – Nag_ComputeZType
   
   On entry: indicates whether the Schur vectors are to be computed.
   
   compz = Nag_NotZ
       No Schur vectors are computed (and the array z is not referenced).
   
   compz = Nag_UpdateZ
       The Schur vectors of A are computed (and the array z must contain the matrix Q on entry).
   
   compz = Nag_InitZ
       The Schur vectors of H are computed (and the array z is initialized by the function).
   
   Constraint: compz = Nag_NotZ, Nag_UpdateZ or Nag_InitZ.

4: n – Integer
   
   On entry: n, the order of the matrix H.
   
   Constraint: n ≥ 0.

5: ilo – Integer

6: ihi – Integer
   
   On entry: if the matrix A has been balanced by nag_zgebal (f08nvc), then ilo and ihi must contain the values returned by that function. Otherwise, ilo must be set to 1 and ihi to n.
   
   Constraint: ilo ≥ 1 and min(ilo, n) ≤ ihi ≤ n.

7: h[dim] – Complex
   
   Note: the dimension, dim, of the array h must be at least max(1, pdh × n).

f08psc.2 Mark 25
Where $H(i,j)$ appears in this document, it refers to the array element

\[ h[(j-1) \times \text{pdh} + i - 1] \]  

when order = Nag_ColMajor;

\[ h[(i-1) \times \text{pdh} + j - 1] \]  

when order = Nag_RowMajor.

On entry: the $n$ by $n$ upper Hessenberg matrix $H$, as returned by nag_zgehrd (f08nsc).

On exit: if job = Nag_EigVals, the array contains no useful information.

If job = Nag_Schur, $h$ is overwritten by the upper triangular matrix $T$ from the Schur decomposition (the Schur form) unless fail.code = NE_CONVERGENCE.

8: \text{pdh} – Integer  

Input

On entry: the stride separating row or column elements (depending on the value of order) in the array $h$.

Constraint: pdh $\geq \max(1, n)$.

9: \text{w}[\text{dim}] – Complex  

Output

Note: the dimension, \text{dim}, of the array \text{w} must be at least $\max(1, n)$.

On exit: the computed eigenvalues, unless fail.code = NE_CONVERGENCE (in which case see Section 6). The eigenvalues are stored in the same order as on the diagonal of the Schur form $T$ (if computed).

10: \text{z}[\text{dim}] – Complex  

Input/Output

Note: the dimension, \text{dim}, of the array \text{z} must be at least

\[
\max(1, \text{pdz} \times n) \quad \text{when compz = Nag_UpdateZ or Nag_InitZ} ; \\
1 \quad \text{when compz = Nag_NotZ} .
\]

The $(i,j)$th element of the matrix $Z$ is stored in

\[ z[(j-1) \times \text{pdz} + i - 1] \]  

when order = Nag_ColMajor;

\[ z[(i-1) \times \text{pdz} + j - 1] \]  

when order = Nag_RowMajor.

On entry: if compz = Nag_UpdateZ, \text{z} must contain the unitary matrix $Q$ from the reduction to Hessenberg form.

If compz = Nag_InitZ, \text{z} need not be set.

On exit: if compz = Nag_UpdateZ or Nag_InitZ, \text{z} contains the unitary matrix of the required Schur vectors, unless fail.code = NE_CONVERGENCE.

If compz = Nag_NotZ, \text{z} is not referenced.

11: \text{pdz} – Integer  

Input

On entry: the stride separating row or column elements (depending on the value of order) in the array \text{z}.

Constraints:

if compz = Nag_UpdateZ or Nag_InitZ, pdz $\geq \max(1, n)$;

if compz = Nag_NotZ, pdz $\geq 1$.

12: \text{fail} – NagError *  

Input/Output

The NAG error argument (see Section 3.6 in the Essential Introduction).
6 Error Indicators and Warnings

**NE_ALLOC_FAIL**
Dynamic memory allocation failed.
See Section 3.2.1.2 in the Essential Introduction for further information.

**NE_BAD_PARAM**
On entry, argument \(\text{value}\) had an illegal value.

**NE_CONVERGENCE**
The algorithm has failed to find all the eigenvalues after a total of \(30(ihi -ilo + 1)\) iterations.

**NE_ENUM_INT_2**
On entry, \(\text{compz} = \langle\text{value}\rangle\), \(\text{pdz} = \langle\text{value}\rangle\) and \(n = \langle\text{value}\rangle\).
Constraint: if \(\text{compz} = \text{Nag}_\text{UpdateZ}\) or \(\text{Nag}_\text{InitZ}\), \(\text{pdz} \geq \max(1,n)\);
if \(\text{compz} = \text{Nag}_\text{NotZ}\), \(\text{pdz} \geq 1\).

**NE_INT**
On entry, \(n = \langle\text{value}\rangle\).
Constraint: \(n \geq 0\).
On entry, \(\text{pdh} = \langle\text{value}\rangle\).
Constraint: \(\text{pdh} > 0\).
On entry, \(\text{pdz} = \langle\text{value}\rangle\).
Constraint: \(\text{pdz} > 0\).

**NE_INT_2**
On entry, \(\text{pdh} = \langle\text{value}\rangle\) and \(n = \langle\text{value}\rangle\).
Constraint: \(\text{pdh} \geq \max(1,n)\).

**NE_INT_3**
On entry, \(n = \langle\text{value}\rangle\), \(ilo = \langle\text{value}\rangle\) and \(ihi = \langle\text{value}\rangle\).
Constraint: \(ilo \geq 1\) and \(\min(ilo,n) \leq ihi \leq n\).

**NE_INTERNAL_ERROR**
An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.
An unexpected error has been triggered by this function. Please contact NAG.
See Section 3.6.6 in the Essential Introduction for further information.

**NE_NO_LICENCE**
Your licence key may have expired or may not have been installed correctly.
See Section 3.6.5 in the Essential Introduction for further information.

7 Accuracy

The computed Schur factorization is the exact factorization of a nearby matrix \((H + E)\), where
\[
\|E\|_2 = O(\epsilon)\|H\|_2,
\]
and \(\epsilon\) is the *machine precision*. 
If \( \lambda_i \) is an exact eigenvalue, and \( \tilde{\lambda}_i \) is the corresponding computed value, then
\[
|\tilde{\lambda}_i - \lambda_i| \leq \frac{c(n)\|H\|_2}{s_i}
\]
where \( c(n) \) is a modestly increasing function of \( n \), and \( s_i \) is the reciprocal condition number of \( \lambda_i \). The condition numbers \( s_i \) may be computed by calling nag_ztrsna (f08qyc).

8 Parallelism and Performance

nag_zhseqr (f08psc) is threaded by NAG for parallel execution in multithreaded implementations of the NAG Library.

nag_zhseqr (f08psc) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users’ Note for your implementation for any additional implementation-specific information.

9 Further Comments

The total number of real floating-point operations depends on how rapidly the algorithm converges, but is typically about:

- \( 25n^3 \) if only eigenvalues are computed;
- \( 35n^3 \) if the Schur form is computed;
- \( 70n^3 \) if the full Schur factorization is computed.

The real analogue of this function is nag_dhseqr (f08pec).

10 Example

This example computes all the eigenvalues and the Schur factorization of the upper Hessenberg matrix \( H \), where
\[
H = \begin{pmatrix}
-3.9700 - 5.0400i & -1.1318 - 2.5693i & -4.6027 - 0.1426i & -1.4249 + 1.7330i \\
-5.4797 + 0.0000i & 1.8585 - 1.5502i & 4.4145 - 0.7638i & -0.4805 - 1.1976i \\
0.0000 + 0.0000i & 6.2673 + 0.0000i & -0.4504 - 0.0290i & -1.3467 + 1.6579i \\
0.0000 + 0.0000i & 0.0000 + 0.0000i & -3.5000 + 0.0000i & 2.5619 - 3.3708i \\
\end{pmatrix}
\]

See also Section 10 in nag_zunghr (f08ntc), which illustrates the use of this function to compute the Schur factorization of a general matrix.
