NAG Library Function Document

nag_double_quantiles (g01amc)

1 Purpose

nag_double_quantiles (g01amc) finds specified quantiles from a vector of unsorted data.

2 Specification

```c
#include <nag.h>
#include <nagg01.h>

void nag_double_quantiles (Integer n, double rv[], Integer nq, const double q[], double qv[], NagError *fail)
```

3 Description

A quantile is a value which divides a frequency distribution such that there is a given proportion of data values below the quantile. For example, the median of a dataset is the 0.5 quantile because half the values are less than or equal to it; and the 0.25 quantile is the 25th percentile.

nag_double_quantiles (g01amc) uses a modified version of Singleton’s ‘median-of-three’ Quicksort algorithm (Singleton (1969)) to determine specified quantiles of a vector of real values. The input vector is partially sorted, as far as is required to compute desired quantiles; for a single quantile, this is much faster than sorting the entire vector. Where necessary, linear interpolation is also carried out to return the values of quantiles which lie between two data points.

4 References

5 Arguments

1:  \( n \) – Integer \( \text{Input} \)

   *On entry:* the number of elements in the input vector \( rv \).

   *Constraint:* \( n > 0 \).

2:  \( rv[n] \) – double \( \text{Input/Output} \)

   *On entry:* the vector whose quantiles are to be determined.

   *On exit:* the order of the elements in \( rv \) is not, in general, preserved.

3:  \( nq \) – Integer \( \text{Input} \)

   *On entry:* the number of quantiles requested.

   *Constraint:* \( nq > 0 \).

4:  \( q[nq] \) – const double \( \text{Input} \)

   *On entry:* the quantiles to be calculated, in ascending order. Note that these must be between 0.0 and 1.0, with 0.0 returning the smallest element and 1.0 the largest.
Constraints:

\[ 0.0 \leq q[i - 1] \leq 1.0, \text{ for } i = 1, 2, \ldots, nq; \]
\[ q[i - 1] \leq q[i], \text{ for } i = 1, 2, \ldots, nq - 1. \]

5: \( qv[nq] \) – double

Output

On exit: \( qv[i - 1] \) contains the quantile specified by the value provided in \( q[i - 1] \), or an interpolated value if the quantile falls between two data values.

6: \( fail \) – NagError *

Input/Output

The NAG error argument (see Section 3.6 in the Essential Introduction).

6 Error Indicators and Warnings

NE_ALLOC_FAIL

Dynamic memory allocation failed.

See Section 3.2.1.2 in the Essential Introduction for further information.

NE_BAD_PARAM

On entry, argument \( \text{value} \) had an illegal value.

NE_INT

On entry, \( n = \text{value} \).

Constraint: \( n > 0 \).

On entry, \( nq = \text{value} \).

Constraint: \( nq > 0 \).

NE_INTERNAL_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.

An unexpected error has been triggered by this function. Please contact NAG.

See Section 3.6.6 in the Essential Introduction for further information.

NE_NO_LICENCE

Your licence key may have expired or may not have been installed correctly.

See Section 3.6.5 in the Essential Introduction for further information.

NE_Q_NOT_ASCENDING

On entry, \( q \) was not in ascending order.

NE_Q_OUT_OF_RANGE

On entry, an element of \( q \) was less than 0.0 or greater than 1.0.

NE_STACK_OVERFLOW

Internal error. Please contact NAG.

7 Accuracy

Not applicable.
8 Parallelism and Performance

Not applicable.

9 Further Comments

The average time taken by nag_double_quantiles (g01amc) is approximately proportional to \( n \times (1 + \log(nq)) \). The worst case time is proportional to \( n^2 \) but this is extremely unlikely to occur.

10 Example

This example computes a list of quantiles from an array of doubles and an array of point values.
