NAG Library Function Document

nag_moving_average (g01wac)

1 Purpose

nag_moving_average (g01wac) calculates the mean and, optionally, the standard deviation using a rolling window for an arbitrary sized data stream.

2 Specification

#include <nag.h>
#include <nagg01.h>

void nag_moving_average (Integer m, Integer nb, const double x[],
                        Nag_Weightstype iwt, const double wt[], Integer *pn,
                        double rmean[], double rsd[], double rcomm[], NagError *fail)

3 Description

Given a sample of \(n\) observations, denoted by \(x = \{x_i : i = 1, 2, \ldots, n\}\) and a set of weights, \(w = \{w_j : j = 1, 2, \ldots, m\}\), nag_moving_average (g01wac) calculates the mean and, optionally, the standard deviation, in a rolling window of length \(m\).

For the \(i\)th window the mean is defined as

\[
\mu_i = \frac{\sum_{j=1}^{m} w_j x_{i+j-1}}{W}
\]

and the standard deviation as

\[
\sigma_i = \sqrt{\frac{\sum_{j=1}^{m} w_j (x_{i+j-1} - \mu_i)^2}{W - \sum_{j=1}^{m} w_j^2} - \frac{(\sum_{j=1}^{m} w_j x_{i+j-1})^2}{W^2}}
\]

with \(W = \sum_{j=1}^{m} w_j\).

Four different types of weighting are possible:

(i) **No weights** \((w_j = 1)\)

When no weights are required both the mean and standard deviations can be calculated in an iterative manner, with

\[
\mu_{i+1} = \mu_i + \frac{(x_{i+m} - x_i)}{m}
\]

\[
\sigma^2_{i+1} = (m-1)\sigma^2_i + \frac{(x_{i+m} - \mu_i)^2 - (x_i - \mu_i)^2 - (x_{i+m} - x_i)^2}{m}
\]

where the initial values \(\mu_1\) and \(\sigma_1\) are obtained using the one pass algorithm of West (1979).

(ii) **Each observation has its own weight**

In this case, rather than supplying a vector of \(m\) weights a vector of \(n\) weights is supplied instead, \(v = \{v_j : j = 1, 2, \ldots, n\}\) and \(w_j = v_{i+j-1}\) in (1) and (2).
If the standard deviations are not required then the mean is calculated using the iterative formula:

\[
W_{i+1} = W_i + (v_{i+m} - v_i)
\]

\[
\mu_{i+1} = \mu_i + W_i^{-1}(v_{i+m}x_{i+m} - v_ix_i)
\]

where \( W_1 = \sum_{i=1}^{m} v_i \) and \( \mu_1 = W_1^{-1} \sum_{i=1}^{m} v_ix_i \).

If both the mean and standard deviation are required then the one pass algorithm of West (1979) is used in each window.

(iii) Each position in the window has its own weight

This is the case as described in (1) and (2), where the weight given to each observation differs depending on which summary is being produced. When these types of weights are specified both the mean and standard deviation are calculated by applying the one pass algorithm of West (1979) multiple times.

(iv) Each position in the window has a weight equal to its position number \( (w_j = j) \)

This is a special case of (iii).

If the standard deviations are not required then the mean is calculated using the iterative formula:

\[
S_{i+1} = S_i + (x_{i+m} - x_i)
\]

\[
\mu_{i+1} = \mu_i + \frac{2(mx_{i+m} - S_i)}{m(m+1)}
\]

where \( S_1 = \sum_{i=1}^{m} x_i \) and \( \mu_1 = \frac{2(m^2 + m)^{-1}}{m(m+1)} S_1 \).

If both the mean and standard deviation are required then the one pass algorithm of West is applied multiple times.

For large datasets, or where all the data is not available at the same time, \( x \) (and if each observation has its own weight, \( v \)) can be split into arbitrary sized blocks and nag_moving_average (g01wac) called multiple times.

4 References

5 Arguments

1: \( m \) – Integer

\textit{Input}

\textit{On entry}: \( m \), the length of the rolling window.

If \( pn \neq 0 \), \( m \) must be unchanged since the last call to nag_moving_average (g01wac).

\textit{Constraint}: \( m \geq 1 \).

2: \( nb \) – Integer

\textit{Input}

\textit{On entry}: \( b \), the number of observations in the current block of data. The size of the block of data supplied in \( x \) (and when \( iwt = \text{Nag\_WeightObs, wt} \)) can vary; therefore \( nb \) can change between calls to nag_moving_average (g01wac).

\textit{Constraints}:

\( nb \geq 0 \);

\text{if } rcomm \text{ is } \text{NULL, } nb \geq m \).

\text{g01wac.2 Mark 25}
On entry: the current block of observations, corresponding to \( x_i \), for \( i = k + 1, \ldots, k + b \), where \( k \) is the number of observations processed so far and \( b \) is the size of the current block of data.

**4:** \( \text{iwt} \) – Nag_Weightstype

On entry: the type of weighting to use.

\( \text{iwt} = \text{Nag}_\text{NoWeights} \)
- No weights are used.

\( \text{iwt} = \text{Nag}_\text{WeightObs} \)
- Each observation has its own weight.

\( \text{iwt} = \text{Nag}_\text{WeightWindow} \)
- Each position in the window has its own weight.

\( \text{iwt} = \text{Nag}_\text{WeightWindowPos} \)
- Each position in the window has a weight equal to its position number.

If \( \text{pn} \neq 0 \), \( \text{iwt} \) must be unchanged since the last call to nag_moving_average (g01wac).

**Constraint:** \( \text{iwt} = \text{Nag}_\text{NoWeights}, \text{Nag}_\text{WeightObs}, \text{Nag}_\text{WeightWindow} \) or \( \text{Nag}_\text{WeightWindowPos} \).

**5:** \( \text{wt}[\text{dim}] \) – const double

**Note:** the dimension, \( \text{dim} \), of the array \( \text{wt} \) must be at least

- \( \text{nb} \) when \( \text{iwt} = \text{Nag}_\text{WeightObs} \);
- \( \text{m} \) when \( \text{iwt} = \text{Nag}_\text{WeightWindow} \);
- otherwise \( \text{wt} \) may be \( \text{NULL} \).

On entry: the user-supplied weights.

If \( \text{iwt} = \text{Nag}_\text{WeightObs} \), \( \text{wt}[i - 1] = \nu_{i+k} \), for \( i = 1, 2, \ldots, b \).

If \( \text{iwt} = \text{Nag}_\text{WeightWindow} \), \( \text{wt}[j - 1] = w_j \), for \( j = 1, 2, \ldots, m \).

Otherwise, \( \text{wt} \) is not referenced and may be \( \text{NULL} \).

**Constraints:**

- if \( \text{iwt} = \text{Nag}_\text{WeightObs} \), \( \text{wt}[i - 1] \geq 0 \), for \( i = 1, 2, \ldots, \text{nb} \);
- if \( \text{iwt} = \text{Nag}_\text{WeightWindow} \), \( \text{wt}[0] \neq 0 \) and \( \sum_{j=1}^{m} \text{wt}[j - 1] > 0 \);
- if \( \text{iwt} = \text{Nag}_\text{WeightWindow} \) and \( \text{rsd} \) is not \( \text{NULL} \), \( \text{wt}[j - 1] \geq 0 \), for \( j = 1, 2, \ldots, m \).

**6:** \( \text{pn} \) – Integer *

On entry: \( k \), the number of observations processed so far. On the first call to nag_moving_average (g01wac), or when starting to summarise a new dataset, \( \text{pn} \) must be set to 0.

If \( \text{pn} \neq 0 \), it must be the same value as returned by the last call to nag_moving_average (g01wac).

On exit: \( k + b \), the updated number of observations processed so far.

**Constraint:** \( \text{pn} \geq 0 \).

**7:** \( \text{rmean}[\text{dim}] \) – double

**Note:** the dimension, \( \text{dim} \), of the array \( \text{rmean} \) must be at least \( \max(0, \text{nb} + \min(0, \text{pn} - \text{m} + 1)) \).

On exit: \( \mu_l \), the (weighted) moving averages, for \( l = 1, 2, \ldots, b + \min(0, k - m + 1) \). Therefore, \( \mu_l \) is the mean of the data in the window that ends on \( x[l + m - \min(k, m - 1) - 2] \).

If, on entry, \( \text{pn} \geq \text{m} - 1 \), i.e., at least one windows worth of data has been previously processed, then \( \text{rmean}[l - 1] \) is the summary corresponding to the window that ends on \( x[l - 1] \). On the other hand, if, on entry, \( \text{pn} = 0 \), i.e., no data has been previously processed, then \( \text{rmean}[l - 1] \) is the
summary corresponding to the window that ends on $x[m+l-2]$ (or, equivalently, starts on $x[l-1]$).

8: $rsd[dim]$ – double

*Output*

Note: the dimension, $dim$, of the array $rsd$ must be at least $\max(0, nb + \min(0, pn - m + 1))$.

Note: if standard deviations are not required then $rsd$ must be NULL.

On exit: if $rsd$ is not NULL then $\sigma_i$, the (weighted) standard deviation. The ordering of $rsd$ is the same as the ordering of $rmean$.

9: $rcomm[2m + 20]$ – double

*Communication Array*

On entry: communication array, used to store information between calls to nag_moving_average (g01wac). If $rcomm$ is NULL then $pn$ must be set to zero and all the data must be supplied in one go.

10: fail – NagError *

*Input/Output*

The NAG error argument (see Section 3.6 in the Essential Introduction).

6 Error Indicators and Warnings

NE_ALLOC_FAIL

Dynamic memory allocation failed.
See Section 3.2.1.2 in the Essential Introduction for further information.

NE_BAD_PARAM

On entry, argument ⟨value⟩ had an illegal value.

NE_ILLEGAL_COMM

$rcomm$ has been corrupted between calls.

NE_INT

On entry, $m = ⟨value⟩$.
Constraint: $m \geq 1$.

On entry, $nb = ⟨value⟩$.
Constraint: $nb \geq 0$.

On entry, $nb = ⟨value⟩$, $m = ⟨value⟩$.
Constraint: if $rcomm$ is NULL, $nb \geq m$.

On entry, $pn = ⟨value⟩$.
Constraint: $pn \geq 0$.

NE_INTERNAL_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.

An unexpected error has been triggered by this function. Please contact NAG.
See Section 3.6.6 in the Essential Introduction for further information.

NE_NEG_WEIGHT

On entry, $wt[⟨value⟩] = ⟨value⟩$.
Constraint: $wt[i-1] \geq 0$. 

if \( p_n > 0 \), \( iwt \) must be unchanged since previous call.

On entry, \( m = \langle \text{value} \rangle \).
On entry at previous call, \( m = \langle \text{value} \rangle \).
Constraint: if \( p_n > 0 \), \( m \) must be unchanged since previous call.

On entry, \( p_n = \langle \text{value} \rangle \).
On exit from previous call, \( p_n = \langle \text{value} \rangle \).
Constraint: if \( p_n > 0 \), \( p_n \) must be unchanged since previous call.

On entry, sum of weights supplied in \( wt \) is \( \langle \text{value} \rangle \).
Constraint: if \( iwt = \text{Nag\_WeightWindow} \), the sum of the weights > 0.

On entry, at least one window had all zero weights.
On entry, unable to calculate at least one standard deviation due to the weights supplied.

Not applicable.

nag\_moving\_average (g01wac) is threaded by NAG for parallel execution in multithreaded implementations of the NAG Library.

nag\_moving\_average (g01wac) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users’ Note for your implementation for any additional implementation-specific information.

The more data that is supplied to nag\_moving\_average (g01wac) in one call, i.e., the larger \( nb \) is, the more efficient the function will be.

This example calculates Spencer’s 15-point moving average for the change in rate of the Earth’s rotation between 1821 and 1850. The data is supplied in three chunks, the first consisting of five observations, the second 10 observations and the last 15 observations.

This example plot shows the smoothing effect of using different length rolling windows on the mean and standard deviation. Two different window lengths, \( m = 5 \) and \( 10 \), are used to produce the unweighted rolling mean and standard deviations for the change in rate of the Earth’s rotation between 1821 and 1850. The values of the rolling mean and standard deviations are plotted at the centre points of their respective windows.

**Example Program**
Raw data, mean and standard deviation from a rolling window of changes in rate of Earth’s rotation (\( \mu s \)), 1821 to 1850

![Example Program](image)
