NAG Library Function Document

nag_regsn_mult_linear_upd_model (g02ddc)

1 Purpose

nag_regsn_mult_linear_upd_model (g02ddc) calculates the regression arguments for a general linear regression model. It is intended to be called after nag_regsn_mult_linear_addrem_obs (g02dcc), nag_regsn_mult_linear_add_var (g02dec) or nag_regsn_mult_linear_delete_var (g02dfc).

2 Specification

```c
#include <nag.h>
#include <nagg02.h>

void nag_regsn_mult_linear_upd_model (Integer n, Integer ip,
    const double q[], Integer tdq, double *rss, double *df, double b[],
    double se[], double cov[], Nag_Boolean *svd, Integer *rank, double p[],
    double tol, NagError *fail)
```

3 Description

A general linear regression model fitted by nag_regsn_mult_linear (g02dac) may be adjusted by adding or deleting an observation using nag_regsn_mult_linear_addrem_obs (g02dcc), adding a new independent variable using nag_regsn_mult_linear_add_var (g02dec) or deleting an existing independent variable using nag_regsn_mult_linear_delete_var (g02dfc). These functions compute the vector \( c \) and the upper triangular matrix \( R \). nag_regsn_mult_linear_upd_model (g02ddc) takes these basic results and computes the regression coefficients, \( \hat{\beta} \), their standard errors and their variance-covariance matrix.

If \( R \) is of full rank, then \( \hat{\beta} \) is the solution to:

\[
R \hat{\beta} = c_1,
\]

where \( c_1 \) is the first \( p \) elements of \( c \).

If \( R \) is not of full rank a solution is obtained by means of a singular value decomposition (SVD) of \( R \),

\[
R = Q_s \begin{pmatrix} D & 0 \\ 0 & 0 \end{pmatrix} P^T
\]

where \( D \) is a \( k \) by \( k \) diagonal matrix with nonzero diagonal elements, \( k \) being the rank of \( R \), and \( Q_s \) and \( P \) are \( p \) by \( p \) orthogonal matrices. This gives the solution

\[
\hat{\beta} = P_1 D^{-1} Q^T_s c_1
\]

\( P_1 \) being the first \( k \) columns of \( P \), i.e., \( P = (P_1 P_0) \) and \( Q_s \), being the first \( k \) columns of \( Q_s \).

Details of the SVD, are made available, in the form of the matrix \( P^* \):

\[
P^* = \begin{pmatrix} D^{-1} P^T_1 \\ P^T_0 \end{pmatrix}
\]

This will be only one of the possible solutions. Other estimates may be obtained by applying constraints to the arguments. These solutions can be obtained by calling nag_regsn_mult_linear_tran_model (g02dnc) after calling nag_regsn_mult_linear_upd_model (g02ddc). Only certain linear combinations of the arguments will have unique estimates, these are known as estimable functions. These can be estimated using nag_regsn_mult_linear_est_func (g02dnc).

The residual sum of squares required to calculate the standard errors and the variance-covariance matrix can either be input or can be calculated if additional information on \( c \) for the whole sample is provided.
4 References

Searle S R (1971) *Linear Models* Wiley

5 Arguments

1: \( n \) – Integer \hspace{1cm} \text{Input}

*On entry:* number of observations.

*Constraint:* \( n \geq 1 \).

2: \( ip \) – Integer \hspace{1cm} \text{Input}

*On entry:* the number of terms in the regression model, \( p \).

*Constraint:* \( ip \geq 1 \).

3: \( q[n \times tdq] \) – const double \hspace{1cm} \text{Input}

*Note:* the \((i,j)\)th element of the matrix \( Q \) is stored in \( q[(i-1) \times tdq + j - 1] \).

*On entry:* \( q \) must be the array \( q \) as output by \text{nag_regsn_mult_linear_adde}m\_obs (g02dcc), \text{nag_regsn_mult_linear_add_var} (g02dec) or \text{nag_regsn_mult_linear_delete_var} (g02dfc).

If on entry \( rss \leq 0.0 \) then all \( n \) elements of \( c \) are needed. This is provided by functions \text{nag_regsn_mult_linear_add_var} (g02dec) or \text{nag_regsn_mult_linear_delete_var} (g02dfc).

4: \( tdq \) – Integer \hspace{1cm} \text{Input}

*On entry:* the stride separating matrix column elements in the array \( q \).

*Constraint:* \( tdq \geq ip + 1 \).

5: \( rss \) – double * \hspace{1cm} \text{Input/Output}

*On entry:* either the residual sum of squares or a value less than or equal to 0.0 to indicate that the residual sum of squares is to be calculated by the function.

*On exit:* if \( rss \leq 0.0 \) on entry, then on exit \( rss \) will contain the residual sum of squares as calculated by \text{nag_regsn_mult_linear_upd_model} (g02ddc).

If \( rss \) was positive on entry, then it will be unchanged.

6: \( df \) – double * \hspace{1cm} \text{Output}

*On exit:* the degrees of freedom associated with the residual sum of squares.

7: \( b[ip] \) – double \hspace{1cm} \text{Output}

*On exit:* the estimates of the \( p \) arguments, \( \hat{\beta} \).

8: \( se[ip] \) – double \hspace{1cm} \text{Output}

*On exit:* the standard errors of the \( p \) arguments given in \( b \).

9: \( cov[ip \times (ip + 1)/2] \) – double \hspace{1cm} \text{Output}

*On exit:* the upper triangular part of the variance-covariance matrix of the \( p \) parameter estimates given in \( b \). They are stored packed by column, i.e., the covariance between the parameter estimate
given in $b[i]$ and the parameter estimate given in $b[j]$, $j \geq i$, is stored in $\text{cov}[j(j + 1)/2 + i]$, for $i = 0, 1, \ldots, \text{ip} - 1$ and $j = i, \ldots, \text{ip} - 1$.

10: $\text{svd} \rightarrow \text{Nag\_Boolean}$ * Output

*On exit:* if a singular value decomposition has been performed, then $\text{svd} = \text{Nag\_TRUE}$, otherwise $\text{svd} = \text{Nag\_FALSE}$.

11: $\text{rank} \rightarrow \text{Integer}$ * Output

*On exit:* the rank of the independent variables.

If $\text{svd} = \text{Nag\_FALSE}$, $\text{rank} = \text{ip}$.

If $\text{svd} = \text{Nag\_TRUE}$, $\text{rank}$ is an estimate of the rank of the independent variables.

$\text{rank}$ is calculated as the number of singular values greater than $\text{tol} \times$ (largest singular value). It is possible for the singular value decomposition to be carried out but $\text{rank}$ to be returned as $\text{ip}$.

12: $p[\text{ip} \times \text{ip} + 2 \times \text{ip}]$ – double

Output

*On exit:* $p$ contains details of the singular value decomposition if used.

If $\text{svd} = \text{Nag\_FALSE}$, $p$ is not referenced.

If $\text{svd} = \text{Nag\_TRUE}$, the first $\text{ip}$ elements of $p$ will not be referenced, the next $\text{ip}$ values contain the singular values. The following $\text{ip} \times \text{ip}$ values contain the matrix $P^*$ stored by rows.

13: $\text{tol} \rightarrow \text{double}$

Input

*On entry:* the value of $\text{tol}$ is used to decide if the independent variables are of full rank and, if not, what is the rank of the independent variables. The smaller the value of $\text{tol}$ the stricter the criterion for selecting the singular value decomposition. If $\text{tol} = 0.0$, then the singular value decomposition will never be used, this may cause run time errors or inaccuracies if the independent variables are not of full rank.

*Suggested value:* $\text{tol} = 0.000001$.

*Constraint:* $\text{tol} \geq 0.0$.

14: $\text{fail} \rightarrow \text{NagError}$ *

Input/Output

The NAG error argument (see Section 3.6 in the Essential Introduction).

6  Error Indicators and Warnings

**NE\_2\_INT\_ARG\_LT**

On entry, $n = \langle\text{value}\rangle$ while $\text{ip} = \langle\text{value}\rangle$. These arguments must satisfy $n \geq \text{ip}$.

On entry, $\text{tdq} = \langle\text{value}\rangle$ while $\text{ip} + 1 = \langle\text{value}\rangle$. These arguments must satisfy $\text{tdq} \geq \text{ip} + 1$.

**NE\_ALLOC\_FAIL**

Dynamic memory allocation failed.

**NE\_DOF\_LE\_ZERO**

The degrees of freedom for error are less than or equal to 0. In this case the estimates, $\hat{\beta}$, are returned but not the standard errors or covariances.

**NE\_INT\_ARG\_LT**

On entry, $\text{ip} = \langle\text{value}\rangle$.

*Constraint:* $\text{ip} \geq 1$. 
On entry, \( n = \langle \text{value} \rangle \).
Constraint: \( n \geq 1 \).

**NE_REAL_ARG_LT**

On entry, \( \text{tol} \) must not be less than 0.0: \( \text{tol} = \langle \text{value} \rangle \).

**NE_SVD_NOT_CONV**

The singular value decomposition has failed to converge. This is an unlikely error exit.

7  Accuracy

The accuracy of the results will depend on the accuracy of the input \( R \) matrix, which may lose accuracy if a large number of observations or variables have been dropped.

8  Parallelism and Performance

Not applicable.

9  Further Comments

None.

10  Example

A dataset consisting of 12 observations and four independent variables is input and a regression model fitted by calls to \texttt{nag_regsn_mult_linear_add_var (g02dec)}. The arguments are then calculated by \texttt{nag_regsn_mult_linear_upd_model (g02ddc)} and the results printed.
