NAG Library Function Document

nag_durbin_watson_stat (g02fcc)

1 Purpose

nag_durbin_watson_stat (g02fcc) calculates the Durbin–Watson statistic, for a set of residuals, and the upper and lower bounds for its significance.

2 Specification

```c
#include <nag.h>
#include <nagg02.h>

void nag_durbin_watson_stat (Integer n, Integer p, const double res[],
                           double *d, double *pdl, double *pdu, NagError *fail)
```

3 Description

For the general linear regression model

\[ y = X\beta + \epsilon, \]

where \( y \) is a vector of length \( n \) of the dependent variable,
\( X \) is a \( n \) by \( p \) matrix of the independent variables,
\( \beta \) is a vector of length \( p \) of unknown arguments,
and \( \epsilon \) is a vector of length \( n \) of unknown random errors.

The residuals are given by

\[ r = y - \hat{y} = y - X\hat{\beta} \]

and the fitted values, \( \hat{y} = X\hat{\beta} \), can be written as \( H y \) for a \( n \) by \( n \) matrix \( H \). Note that when a mean term is included in the model the sum of the residuals is zero. If the observations have been taken serially, that is \( y_1, y_2, \ldots, y_n \) can be considered as a time series, the Durbin–Watson test can be used to test for serial correlation in the \( \epsilon_i \), see Durbin and Watson (1950), Durbin and Watson (1951) and Durbin and Watson (1971).

The Durbin–Watson statistic is

\[ d = \frac{\sum_{i=1}^{n-1} (r_{i+1} - r_i)^2}{\sum_{i=1}^{n} r_i^2}. \]

Positive serial correlation in the \( \epsilon_i \) will lead to a small value of \( d \) while for independent errors \( d \) will be close to 2. Durbin and Watson show that the exact distribution of \( d \) depends on the eigenvalues of the matrix \( HA \) where the matrix \( A \) is such that \( d \) can be written as

\[ d = \frac{r^T Ar}{r^T r} \]

and the eigenvalues of the matrix \( A \) are \( \lambda_j = (1 - \cos(\pi j/n)) \), for \( j = 1, 2, \ldots, n - 1. \)
However bounds on the distribution can be obtained, the lower bound being

\[
d_l = \frac{\sum_{i=1}^{n-p} \lambda_i u_i^2}{\sum_{i=1}^{n-p} u_i^2}
\]

and the upper bound being

\[
d_u = \frac{\sum_{i=1}^{n-p} \lambda_{i-1+p} u_i^2}{\sum_{i=1}^{n-p} u_i^2},
\]

where the \( u_i \) are independent standard Normal variables. The lower tail probabilities associated with these bounds, \( p_l \) and \( p_u \), are computed by \texttt{nag_prob_durbin_watson (g01epc)}. The interpretation of the bounds is that, for a test of size (significance) \( \alpha \), if \( p_l \leq \alpha \) the test is significant, if \( p_u > \alpha \) the test is not significant, while if \( p_l > \alpha \) and \( p_u \leq \alpha \) no conclusion can be reached.

The above probabilities are for the usual test of positive auto-correlation. If the alternative of negative auto-correlation is required, then a call to \texttt{nag_prob_durbin_watson (g01epc)} should be made with the argument \( d \) taking the value of \( 4 - d \); see Newbold (1988).

5 Arguments

1: \( n \) – Integer \hspace{1cm} Input

\textit{On entry}: \( n \), the number of residuals.

\textit{Constraint}: \( n > p \).

2: \( p \) – Integer \hspace{1cm} Input

\textit{On entry}: \( p \), the number of independent variables in the regression model, including the mean.

\textit{Constraint}: \( p \geq 1 \).

3: \( \text{res}[\text{n}] \) – const double \hspace{1cm} Input

\textit{On entry}: the residuals, \( r_1, r_2, \ldots, r_n \).

\textit{Constraint}: the mean of the residuals \( \leq \sqrt{\epsilon} \), where \( \epsilon = \text{machine precision} \).

4: \( d \) – double * \hspace{1cm} Output

\textit{On exit}: the Durbin–Watson statistic, \( d \).
5:  pdl – double *
    
    On exit: lower bound for the significance of the Durbin–Watson statistic, \( p_l \).

6:  pdu – double *
    
    On exit: upper bound for the significance of the Durbin–Watson statistic, \( p_u \).

7:  fail – NagError *
    
    The NAG error argument (see Section 3.6 in the Essential Introduction).

6  Error Indicators and Warnings

NE_ALLOC_FAIL
    Dynamic memory allocation failed.
    See Section 3.2.1.2 in the Essential Introduction for further information.

NE_BAD_PARAM
    On entry, argument \( \langle \text{value} \rangle \) had an illegal value.

NE_INT
    On entry, \( p = \langle \text{value} \rangle \).
    Constraint: \( p \geq 1 \).

NE_INT_2
    On entry, \( n = \langle \text{value} \rangle \) and \( p = \langle \text{value} \rangle \).
    Constraint: \( n > p \).

NE_INTERNAL_ERROR
    An internal error has occurred in this function. Check the function call and any array sizes. If the
call is correct then please contact NAG for assistance.

    An unexpected error has been triggered by this function. Please contact NAG.
    See Section 3.6.6 in the Essential Introduction for further information.

NE_NO_LICENCE
    Your licence key may have expired or may not have been installed correctly.
    See Section 3.6.5 in the Essential Introduction for further information.

NE_RESID_IDEN
    On entry, all residuals are identical.

NE_RESID_MEAN
    On entry, the mean of \( \text{res} \) is not approximately 0.0, \( \text{mean} = \langle \text{value} \rangle \).

7  Accuracy

The probabilities are computed to an accuracy of at least 4 decimal places.

8  Parallelism and Performance

Not applicable.
9 Further Comments

If the exact probabilities are required, then the first \( n - p \) eigenvalues of \( HA \) can be computed and nag_prob_lin_chi_sq (g01jdc) used to compute the required probabilities with the argument \( c \) set to 0.0 and the argument \( d \) set to the Durbin–Watson statistic \( d \).

10 Example

A set of 10 residuals are read in and the Durbin–Watson statistic along with the probability bounds are computed and printed.
