# **NAG Library Function Document**

# nag\_opt\_one\_var\_deriv (e04bbc)

## **1** Purpose

nag\_opt\_one\_var\_deriv (e04bbc) searches for a minimum, in a given finite interval, of a continuous function of a single variable, using function and first derivative values. The method (based on cubic interpolation) is intended for functions which have a continuous first derivative (although it will usually work if the derivative has occasional discontinuities).

## 2 Specification

```
#include <nag.h>
#include <nage04.h>
void nag_opt_one_var_deriv (
    void (*funct)(double xc, double *fc, double *gc, Nag_Comm *comm),
    double e1, double e2, double *a, double *b, Integer max_fun, double *x,
    double *f, double *g, Nag_Comm *comm, NagError *fail)
```

## 3 Description

nag\_opt\_one\_var\_deriv (e04bbc) is applicable to problems of the form:

Minimize F(x) subject to  $a \le x \le b$ 

when the first derivative dF/dx can be calculated. nag\_opt\_one\_var\_deriv (e04bbc) normally computes a sequence of x values which tend in the limit to a minimum of F(x) subject to the given bounds. It also progressively reduces the interval [a, b] in which the minimum is known to lie. It uses the safeguarded quadratic-interpolation method described in Gill and Murray (1973).

You must supply a function **funct** to evaluate F(x) and its first derivative. The arguments **e1** and **e2** together specify the accuracy:

 $Tol(x) = \mathbf{e1} \times |x| + \mathbf{e2}$ 

to which the position of the minimum is required. Note that **funct** is never called at any point which is closer than Tol(x) to a previous point.

If the original interval [a, b] contains more than one minimum, nag\_opt\_one\_var\_deriv (e04bbc) will normally find one of the minima.

### 5 Arguments

1: **funct** – function, supplied by the user

External Function

funct must calculate the values of F(x) and dF/dx at any point x in [a, b].

The specification of **funct** is: void funct (double xc, double \*fc, double \*gc, Nag\_Comm \*comm)

Mark 26

1:	$\mathbf{xc}$ - double Input On antra: $\mathbf{x}$ the point at which the values of $\mathbf{F}$ and $d\mathbf{F}/d\mathbf{r}$ are required	ıt
2:	$\mathbf{fc}$ - double * Output Outp	ıt
3:	gc – double * Output On exit: the value of the first derivative $dF/dx$ at the current point x.	ıt
4:	<pre>comm - Nag_Comm * Pointer to structure of type Nag Comm: the following members are relevant to function </pre>	f
	first – Nag_Boolean Input	ı. It
	On entry: will be set to Nag_IRUE on the first call to <b>funct</b> and Nag_FALSE to all subsequent calls.	r 
	On entry: the number of calls made to <b>funct</b> so far.	:L
	user – double * iuser – Integer * p – Pointer	
	The type Pointer will be void * with a C compiler that defines void * an char * otherwise. Before calling nag_opt_one_var_deriv (e04bbc) these pointer may be allocated memory and initialized with various quantities for use by <b>func</b> when called from nag_opt_one_var_deriv (e04bbc).	d s t

**Note: funct** should be tested separately before being used in conjunction with nag\_opt\_one\_var\_deriv (e04bbc).

2: **e1** – double

*On entry*: the relative accuracy to which the position of a minimum is required. (Note that since e1 is a relative tolerance, the scaling of x is automatically taken into account.)

It is recommended that e1 should be no smaller than  $2\epsilon$ , and preferably not much less than  $\sqrt{\epsilon}$ , where  $\epsilon$  is the *machine precision*.

If e1 is set to a value less than  $\epsilon$ , its value is ignored and the default value of  $\sqrt{\epsilon}$  is used instead. In particular, you may set e1 = 0.0 to ensure that the default value is used.

3: **e2** – double

On entry: the absolute accuracy to which the position of a minimum is required. It is recommended that  $e^2$  should be no smaller than  $2\epsilon$ .

If e2 is set to a value less than  $\epsilon$ , its value is ignored and the default value of  $\sqrt{\epsilon}$  is used instead. In particular, you may set  $e^2 = 0.0$  to ensure that the default value is used.

4: **a** – double \*

On entry: the lower bound a of the interval containing a minimum.

On exit: an improved lower bound on the position of the minimum.

5: **b** – double \*

On entry: the upper bound b of the interval containing a minimum.

Input

Input/Output

Input/Output

Input

On exit: an improved upper bound on the position of the minimum.

Constraint:  $\mathbf{b} > \mathbf{a} + \mathbf{e2}$ .

Note that the value  $e^2 = \sqrt{\epsilon}$  applies here if  $e^2 < \epsilon$  on entry to nag\_opt\_one\_var\_deriv (e04bbc).

#### 6: **max\_fun** – Integer

On entry: the maximum number of calls to funct which you are prepared to allow.

The number of calls to **funct** actually made by nag\_opt\_one\_var\_deriv (e04bbc) may be determined by supplying a non-NULL argument **comm** (see below) and examining the structure member **comm** $\rightarrow$ **nf** on exit.

*Constraint*:  $max_fun \ge 2$ 

(Few problems will require more than 20 function calls.)

#### 7: $\mathbf{x} - \text{double }^*$

On exit: the estimated position of the minimum.

8:  $\mathbf{f}$  – double \*

On exit: the value of F at the final point  $\mathbf{x}$ .

9:  $\mathbf{g}$  - double \*

On exit: the value of the first derivative dF/dx at the final point **x**.

10: **comm** – Nag Comm \*

**Note: comm** is a NAG defined type (see Section 2.3.1.1 in How to Use the NAG Library and its Documentation).

*On entry/exit*: structure containing pointers for communication to user-supplied functions; see the above description of **funct** for details. The number of times the function **funct** was called is returned in the member **comm** $\rightarrow$ **nf**.

If you do not need to make use of this communication feature, the null pointer NAGCOMM\_NULL may be used in the call to nag\_opt\_one\_var\_deriv (e04bbc); comm will then be declared internally for use in calls to user-supplied functions.

11: fail – NagError \*

The NAG error argument (see Section 2.7 in How to Use the NAG Library and its Documentation).

### 6 Error Indicators and Warnings

#### NE\_2\_REAL\_ARG\_GE

On entry,  $\mathbf{a} + \mathbf{e2} = \langle value \rangle$  while  $\mathbf{b} = \langle value \rangle$ . These arguments must satisfy  $\mathbf{a} + \mathbf{e2} < \mathbf{b}$ .

### NE\_INT\_ARG\_LT

On entry, **max\_fun** must not be less than 2: **max\_fun** =  $\langle value \rangle$ .

### NW\_MAX\_FUN

The maximum number of function calls, (value), have been performed.

This may have happened simply because **max\_fun** was set too small for a particular problem, or may be due to a mistake in the user-supplied function, **funct**. If no mistake can be found in **funct**, restart nag\_opt\_one\_var\_deriv (e04bbc) (preferably with the values of **a** and **b** given on exit from the previous call to nag\_opt\_one\_var\_deriv (e04bbc)).

## 7 Accuracy

If F(x) is  $\delta$ -unimodal for some  $\delta < Tol(x)$ , where  $Tol(x) = \mathbf{e1} \times |x| + \mathbf{e2}$ , then, on exit, x approximates the minimum of F(x) in the original interval [a, b] with an error less than  $3 \times Tol(x)$ .

## 8 Parallelism and Performance

nag\_opt\_one\_var\_deriv (e04bbc) is not threaded in any implementation.

## 9 Further Comments

Timing depends on the behaviour of F(x), the accuracy demanded, and the length of the interval [a, b]. Unless F(x) and dF/dx can be evaluated very quickly, the run time will usually be dominated by the time spent in **funct**.

If F(x) has more than one minimum in the original interval [a, b], nag\_opt\_one\_var\_deriv (e04bbc) will determine an approximation x (and improved bounds a and b) for one of the minima.

If nag\_opt\_one\_var\_deriv (e04bbc) finds an x such that  $F(x - \delta_1) > F(x) < F(x + \delta_2)$  for some  $\delta_1, \delta_2 \ge Tol(x)$ , the interval  $[x - \delta_1, x + \delta_2]$  will be regarded as containing a minimum, even if F(x) is less than  $F(x - \delta_1)$  and  $F(x + \delta_2)$  only due to rounding errors in the user-supplied function. Therefore funct should be programmed to calculate F(x) as accurately as possible, so that nag\_opt\_one\_var\_deriv (e04bbc) will not be liable to find a spurious minimum. (For similar reasons, dF/dx should be evaluated as accurately as possible.)

## 10 Example

A sketch of the function

$$F(x) = \frac{\sin x}{x}$$

shows that it has a minimum somewhere in the range [3.5, 5.0]. The example program below shows how nag\_opt\_one\_var\_deriv (e04bbc) can be used to obtain a good approximation to the position of a minimum.

### 10.2 Program Data

None.

## 10.3 Program Results

nag\_opt\_one\_var\_deriv (e04bbc) Example Program Results

(User-supplied callback funct, first invocation.) The minimum lies in the interval 4.49341 to 4.49341. Its estimated position is 4.49341, where the function value is -2.1723e-01 and the gradient is -3.7679e-16. 6 function evaluations were required.
